Modern cosmology in a nutshell:

Edwin Hubble

1) The universe is expanding.
(Hubble, 1920s)

2) It was once hot and dense, like the inside of the Sun.

(Alpher, Gamow, Herman, 1940s)

3) You can still see the glow!
The Cosmic Microwave Background
(Penzias & Wilson, 1964)

History of the Universe

CMB Temperature Measurements / Inflation

CMB temperature anisotropy now measured over full range of angular scales.

Consistent with Λ CDM paradigm(?) and constrains its parameters to sub percent accuracy.

Inflation “invented” in 1980s to explain facts about the Universe which were known or suspected.

Makes additional prediction of a background of gravitational waves (aka tensor modes) – which will imprint a specific CMB polarization pattern...

→ so-called “smoking gun”

→ amplitude tells us the energy scale at which inflation occurred

Planck Collaboration & ESA

Why Inflation?

Solves the horizon problem:
Why is the CMB nearly uniform?
How do apparently causally disconnected regions of space get set to the same temperature?

A volume much larger than our entire observable universe today was once a causally connected sub atomic spec.

Solves the flatness problem:
Why is the net spatial curvature close to zero?

Any initial spatial curvature is diluted away to undetectability by the hyper expansion.

Explains the initial perturbation spectrum: Why was it close to flat power law?

Equal amount of perturbations are injected at each step in the exponential expansion.

Solves the monopole problem:
Why do we not observe magnetic monopoles in the Universe today?

Monopoles are diluted away to undetectability.

**CMB polarization:
arises at last scattering
from local radiation quadrupole**

CMB polarization

Density Wave

E-Mode Polarization Pattern

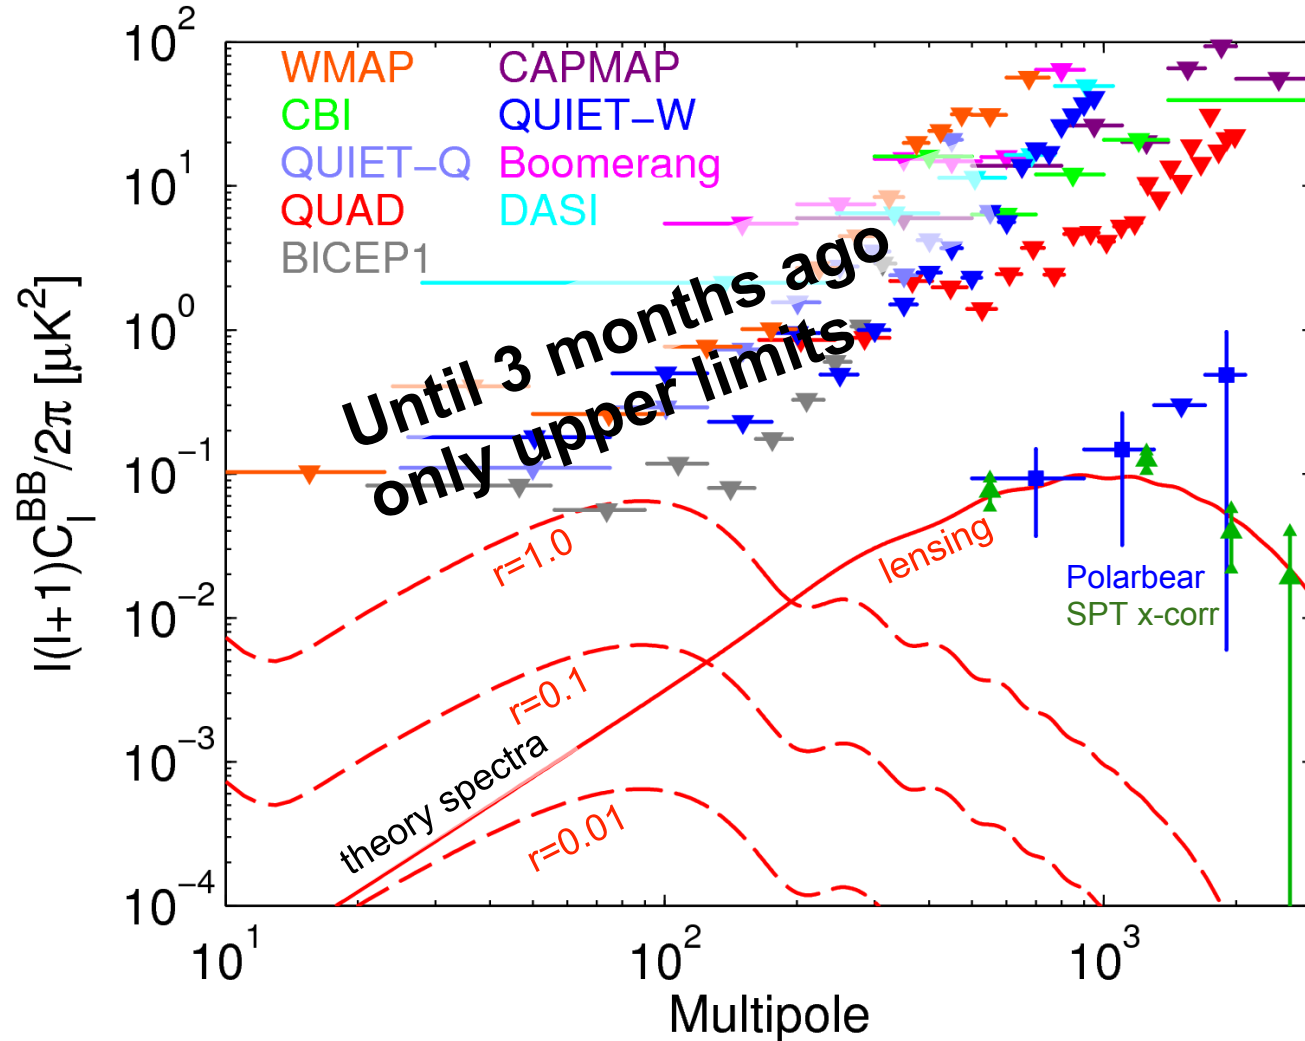

Gravitational Wave

B-Mode Polarization Pattern

The long search for Inflationary B-modes

In simple inflationary gravitational wave models the

tensor-to-scalar ratio r

is the only parameter to the B-mode spectrum.

Until recently only upper limits from searches for Inflationary B-modes

Best previous limit on r from BICEP1:

$r < 0.7$ (95% CL)

Note at high multipoles lensing B-mode dominant.

SPT x-corr: lower limits on lensing B-mode from cross correlation using the CIB

B-modes from the ground

- Deep, Concentrated coverage
 - Foreground avoidance (limited frequency)
 - Systematic control with in-situ calibration
 - Large detector count, rapid technology cycle
 - Relentless observing & large number of null tests
- powerful recipe for high-confidence initial discovery

South Pole CMB telescopes

NSF's South Pole Station:
A popular place with CMB Experimentalists!

Super dry atmosphere and 24h coverage of “Southern Hole”.
Also power, LHe, LN₂, 200 GB/day, 3 square meals, and bingo night...

BICEP2 Experimental Concept

- Small aperture
- Wide field of view
- Cold refractor

Mass-produced superconducting detectors

Slot antennas

Transition edge sensor

Microstrip filters

BICEP2 Sensitivity

Histogram shows per-detector noise equivalent temperature (NET) for data taken in 2012

Our recipe for high sensitivity:

- High optical efficiency
40% end-to-end
- Cold optics
Low loading/photon noise
Low thermal conductance,
and thus low phonon noise
- High detector count

Total Sensitivity for full BICEP2 instrument: $15.8 \mu K \sqrt{s}$

Observational Strategy

Target the “Southern Hole” - a region of the sky exceptionally free of dust and synchrotron foregrounds.

Detectors tuned to 150 GHz, near the peak of the CMB’s 2.7 K blackbody spectrum.

Sync falls with increasing frequency while dust rises – cross over below 150 GHz

Clem Pryke for The Bicep2 Collaboration

Raw Data - Perfect Weather

Time 50 mins

- Cover the whole field in 60 such scans
then start over at new boresight rotation

- Scanning modulated the CMB signal to freqs < 4 Hz

Raw Data - Worse Weather

Time 50 mins

Run 20120622D01_dk293, scan block 1; Rx: 0

➤ Scanning over lumpy atmosphere
→ “clouds”

➤ Pair difference still clean
→ atmosphere is unpolarized

BICEP2 on the Sky

Projection of the BICEP2 focal plane on the sky

The focal plane is 20 degrees across

Background is the CMB temperature map as measured with BICEP2

Data Quality Cuts

Cut parameter	Total time [10^6 s]	Integration [10^9 det · s]	Fraction cut [%]
Before cuts	36.5	14.8	—
Channel cuts	36.5	13.2	10.9
Synchronization	35.3	12.7	3.1
Deglitching	33.6	10.7	13.8
Per-scan noise	33.6	10.7	< 0.01%
Passing channels	33.3	10.7	0.22
Manual cut	33.0	10.6	0.43
Elevation nod	31.0	9.2	9.5
Fractional resistance	31.0	9.2	0.16
Skewness	31.0	9.1	0.41
Time stream variance	30.9	9.0	0.52
Correlated noise	30.9	9.0	< 0.01%
Noise stationarity	30.7	8.9	0.64
FPU temperature	30.6	8.9	0.20
Passing data	27.6	8.6	1.7

3 years of data!

Multistage cut procedure:

Ensures all data used in map making is taken when the experiment is operating properly and has stationary, well-behaved noise

Many cuts identify periods of exceptionally bad weather and are redundant.

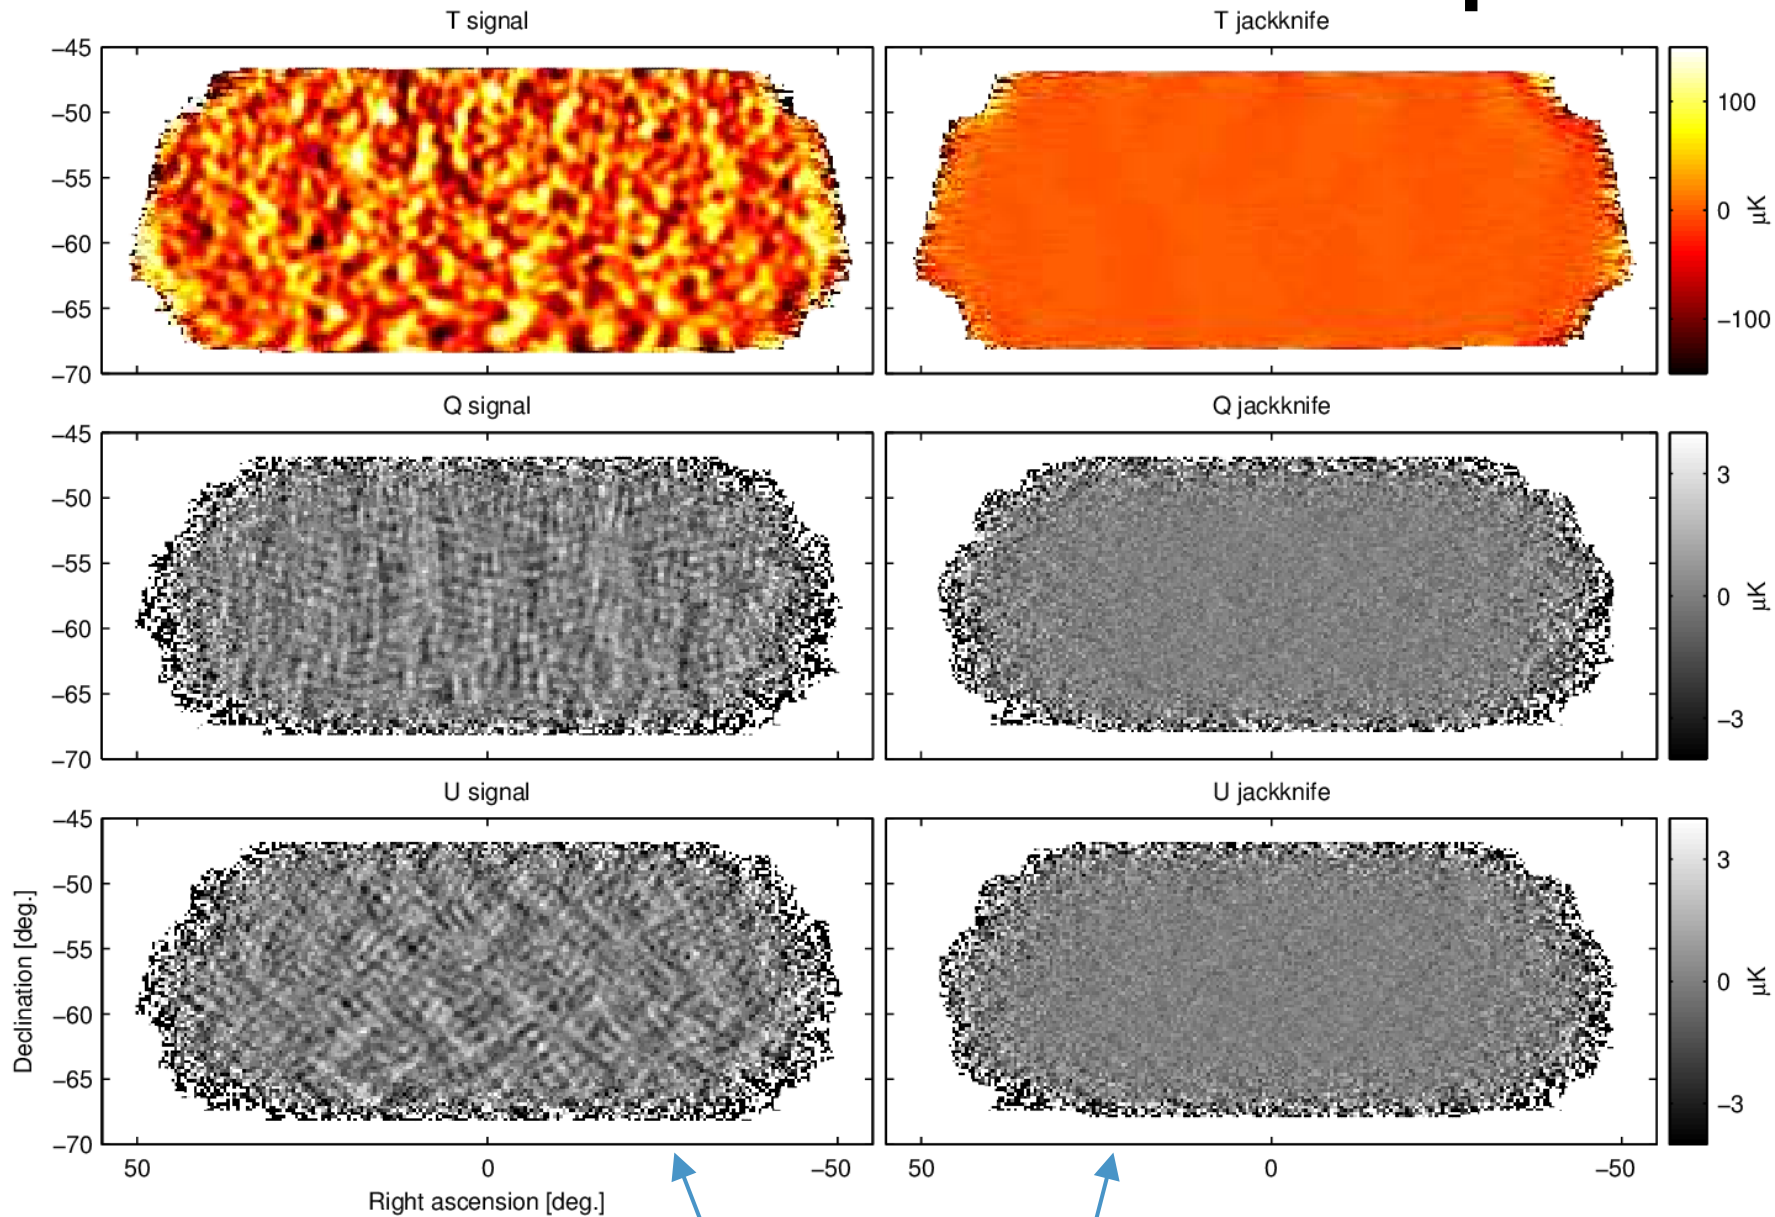

BICEP2 data very well-behaved:
pass fraction = 63%

Table from Instrument Paper

BICEP2 3-year Data Set

BICEP2 T and Stokes Q/U Maps

Total Polarization

B-mode Contribution

BICEP2 B-mode signal

Scale: $1.7 \mu K$

Apply purification operation to Q/U maps which leaves only pure B-modes
(given all timestream filterings etc.)

B-mode Contribution

BICEP2 B-mode signal

Scale: $0.3 \mu K$

Zoom in by factor 6 – see “swirly” B-mode

B-mode Map vs. Simulation

Analysis “calibrated” using lensed- Λ CDM+noise simulations.

The simulations repeat the full observation at the timestream level - including all filtering operations.

We perform various filtering operations: Use the sims to correct for these

Also use the sims to derive the final uncertainties (error bars)

BICEP2 B-mode Power Spectrum

- B-mode power spectrum
- temporal split jackknife
- lensed- Λ CDM
- - - $r=0.2$

B-mode power spectrum estimated from Q&U maps, including map based “purification” to avoid $E \rightarrow B$ mixing

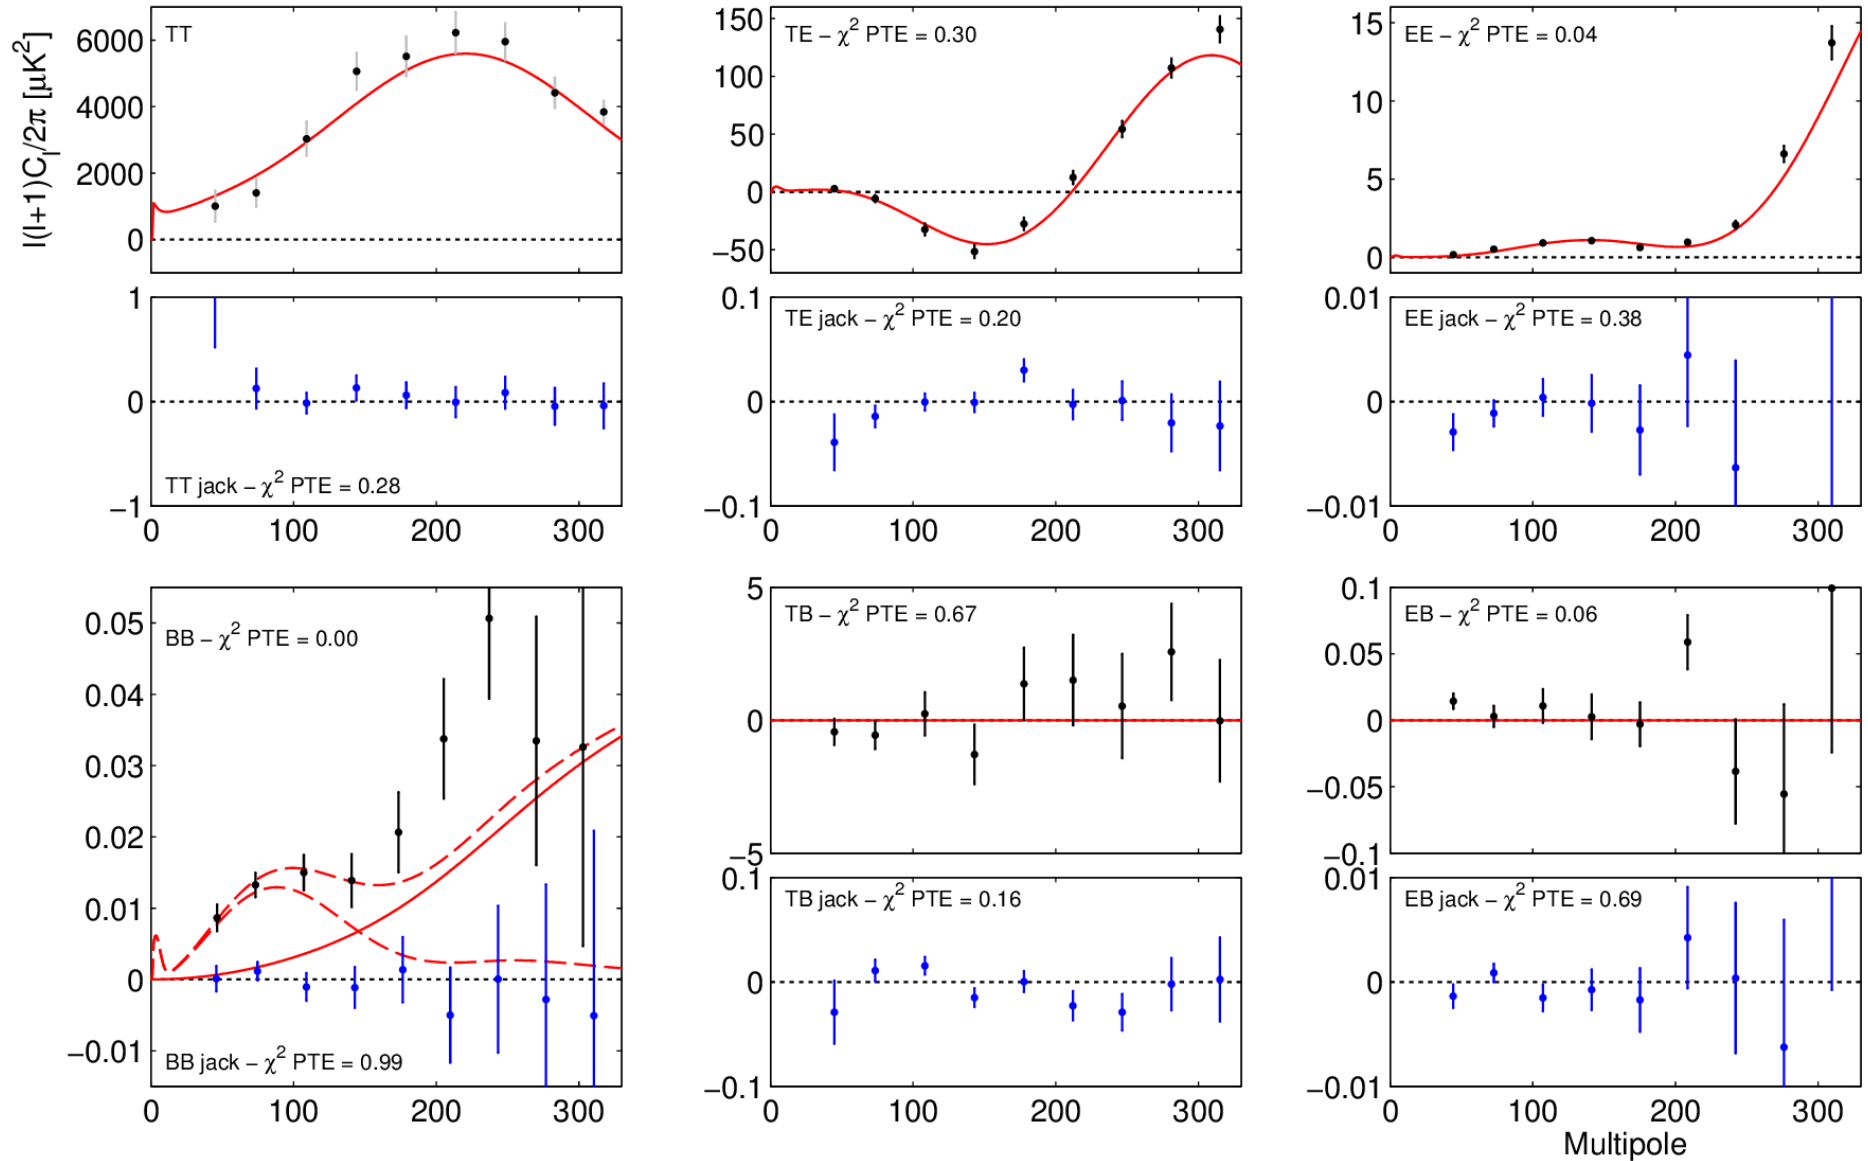

Consistent with lensing expectation at higher l . (yes – a few points are high but not excessively...)

At low l excess over lensed- Λ CDM with high signal-to-noise.

For the hypothesis that the measured band powers come from lensed- Λ CDM we find:

χ^2 PTE	1.3×10^{-7}
significance	5.3σ

Temperature and Polarization Spectra

● power spectra
 ● temporal split jackknife
 — lensed- ΛCDM
 - - $r=0.2$

Bandpower Deviations

Bandpower deviations from mean of lensed- Λ CDM
+noise simulations and normalized by the std of
those sims

- real data
- lensed- Λ CDM + noise sims
- $\pm 1\sigma$
- $\pm 2\sigma$

Splits the 4 boresight rotations

Amplifies differential pointing in comparison to fully added data. Important check of deprojection. See later slides.

Splits by time

Checks for contamination on long (“Temporal Split”) and short (“Scan Dir”) timescales. Short timescales probe detector transfer functions.

Splits by channel selection

Checks for contamination in channel subgroups, divided by focal plane location, tile location, and readout electronics grouping

Splits by possible external contamination

Checks for contamination from ground-fixed signals, such as polarized sky or magnetic fields, or the moon

Splits to check intrinsic detector properties

Checks for contamination from detectors with best/worst differential pointing. “Tile/dk” divides the data by the orientation of the detector on the sky.

Systematics paper nearly ready – and see Chris Sheehy poster

Calibration Measurements

For instance...

Far field beam mapping

Hi-Fi beam maps of
individual detectors

**Detailed description in
companion Instrument Paper**

Detector Polarization Calibration

Channel 235

Systematics Removal: Deprojection

Technique developed to remove all types of leakage induced by differences of detector pair beam shapes

Use the Planck 143 GHz map to form template of the leakage

Deproject diff gain and pointing (& subtract diff ellipticity)

Subtract the residual (equiv to $r=0.001$) from the data

Systematics beyond Beam imperfections

All systematic effects that we could imagine were investigated!

We find with high confidence that the apparent signal *cannot be explained* by instrumental systematics!

Polarized Dust Foreground Projections

The BICEP2 region was chosen to on the basis of extremely low unpolarized dust power.

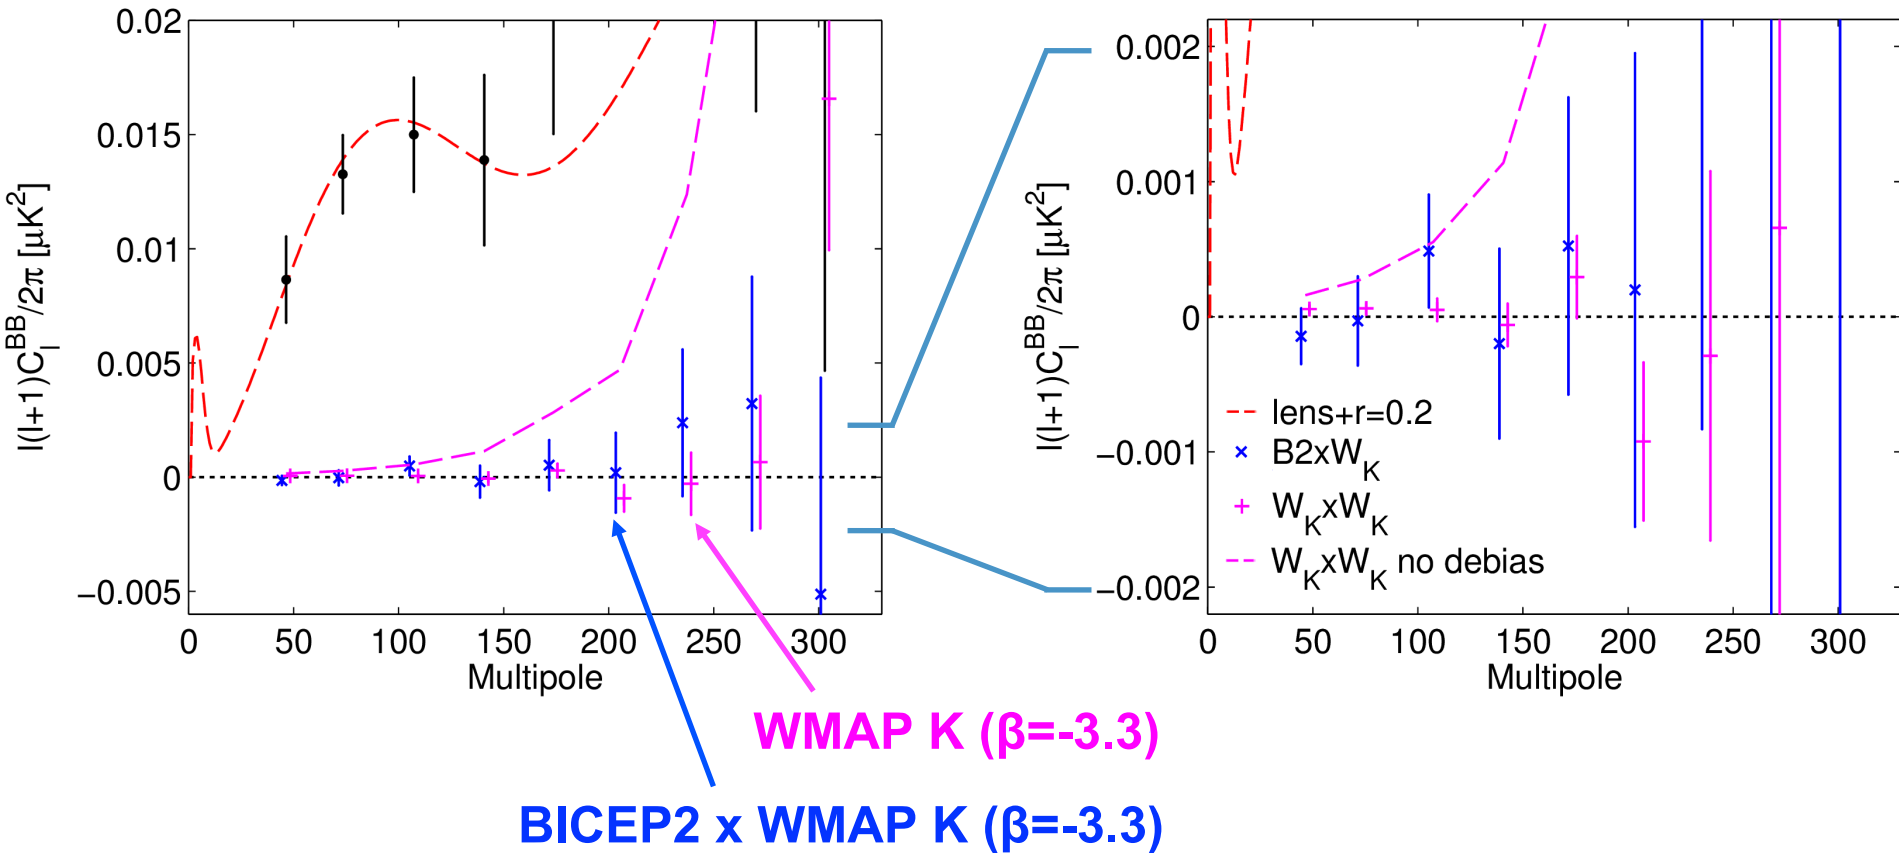

Use various models of polarized dust emission to estimate dust power.

Result: All dust auto spectra well below observed signal level. (and cross spectra consistent with zero.)

But considerable uncertainty remains...

Synchrotron Foreground

BICEP2 x WMAP 22 GHz polarization (extrapolated to 150 GHz with $\beta=-3.3^*$) is noise dominated but limits synchrotron to $r < 0.0008$.

The Bicep2 Collaboration
 $\beta = -3.3$ is the mean sync spectral index given by WMAP within BICEP2 field

Cross Correlation with BICEP1

Though less sensitive, BICEP1 applied **different technology** (systematics control) and **multiple colors** (foreground control) to the **same sky**.

BICEP2: Phased antenna array and TES readout
150 GHz

BICEP1: Feedhorns
and NTD readout
150 and 100 GHz

Cross-correlations with both colors are **consistent** with the B2 auto spectrum

Cross with BICEP1₁₀₀ shows **~3σ** detection of BB power

Spectral Index of the B-mode Signal

Comparison of B2 auto with B2₁₅₀ x B1₁₀₀ constrains signal frequency dependence, independent of foreground projections

If **dust**, expect little cross-correlation

If **synchrotron**, expect cross higher than auto

Likelihood ratio test: consistent with CMB spectrum, disfavor pure dust/sync at **1.7/1.6 σ**

green: total signal

black : excess signal over Λ CDM

Cross Spectra between 3 Experiments

Form cross spectrum between BICEP2 and
BICEP1 combined (100 + 150 GHz):

BICEP2 auto spectrum compatible with
B2xB1c cross spectrum
~3 σ evidence of excess power in the
cross spectrum

Additionally form cross spectrum with
2 years of data from *Keck Array*, the
successor to BICEP2

Excess power is also evident in the
B2xKeck cross spectrum

Cross spectra:
**Powerful additional evidence against a
systematic origin of the apparent signal**

Constraint on Tensor-to-scalar Ratio r

Substantial excess power in the region where the inflationary gravitational wave signal is expected to peak

Find the most likely value of the tensor-to-scalar ratio r

Apply “direct likelihood” method, uses:

- lensed- Λ CDM + noise simulations
- weighted version of the 5 bandpowers
- B-mode sims scaled to various levels of r ($n_T=0$)

Within this simplistic model we find:

$r = 0.2$ with uncertainties dominated by sample variance

PTE of fit to data: 0.9

→ model is perfectly acceptable fit to the data

$r = 0$ ruled out at 7.0σ

Constraint on r under Foreground Projections

Adjust likelihood curve by subtracting the dust projection auto and cross spectra from our bandpowers:

Probability that each of these models reflect reality is hard to assess.

DDM1 uses all publicly available information from Planck. Polarization fraction here assumed $p = 5\%$. $p \sim 13\%$ would explain the full excess under this model.

Dust contribution is largest in the first bandpower. Deweighting this bin would lead to less deviation from our base result.

Compatibility with Temperature Based Limits on r

Using temperature data over a wide range of angular scales limits on r have been set:

SPT+WMAP+BAO+ H_0 : $r < 0.11$

Planck+SPT+ACT+WMAP_{pol} : $r < 0.11$

(95% CL)

However, $r=0.2$ just makes a small change to the temperature spectrum.

(In this plot $r=0.2$ simply added to Planck best fit model with no re-optimization of other parameters)

Compatibility with Temperature Based Limits on r

Constraint on r with *running* allowed:

This apparent tension can be relieved with various extensions to lensed- Λ CDM.

Example: running of the spectral index

Planck likelihood chains for lensed Λ CDM + *tensors* + *running*

Same chains, importance sampled with the BICEP2 r likelihood

Other possibilities within Λ CDM?...

Conclusions circa March 17th

BICEP2 and upper limits from other experiments:

<http://bicepkeck.org>

Most sensitive polarization maps ever made

Power spectra perfectly consistent with lensed- Λ CDM except:
5.2 σ excess in the B-mode spectrum at low multipoles!

Extensive studies and jackknife tests strongly argue against systematics as the origin

Foregrounds do not appear to be a large fraction of the signal:

- foreground projections
- lack of cross correlations
- CMB-like spectral index
- spatial and spectral shape of the B-mode signal

Constraint on tensor-to-scalar ratio r in simple inflationary gravitational wave model:

$$r = 0.20^{+0.07}_{-0.05}$$

With $r=0$ is ruled out at 7.0 σ .

Developments Since...

- Intense media and science community interest...
- Many early instrumental queries... mostly seem to have faded
- Since our release papers on dust polarization have appeared from Planck
 - But specifically mask out low foreground regions like ours (due to “non small systematics and not dust dominated”)
- Concerns with our result seem to have boiled down to:
 - Spectral index constraint includes lensing signal – true – but a small effect
 - Polarized dust foreground may be stronger than previously projected...
- Last Thursday our paper published in PRL (and updated on the arxiv)
- Keck 2014 is running right now with 2 receivers at 100GHz
 - Sensitivity of BICEP1 already surpassed
 - We plan an analysis asap which will tighten spectral index constraint
- Meanwhile many other experiments in the running:
 - Full Planck release by the end of the year (and maybe another dust paper sooner)
