

# Studying the Beginning of the Universe from the Bottom of the World Clem Pryke - Astro Colloquium, Durham - May 29 2024

## Modern cosmology in a nutshell:

Edwin Hubble

1) The universe is expanding. (Hubble, 1920s)

2) It was once hot and dense, like the inside of the Sun.

(Alpher, Gamow, Herman, 1940s)

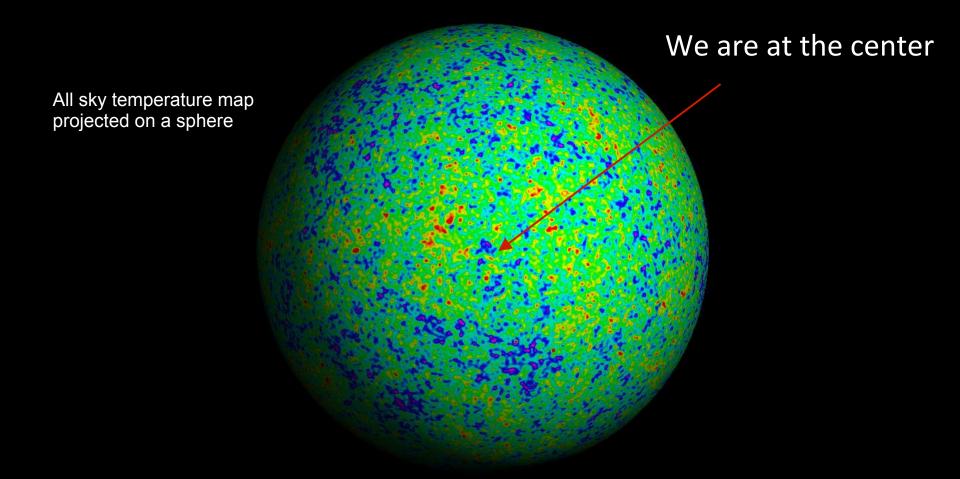

3) We can see the (redshifted) glow! The Cosmic Microwave Background (Penzias & Wilson, 1964)

Bob Wilson & Arno Penzias 1978 Nobel Prize

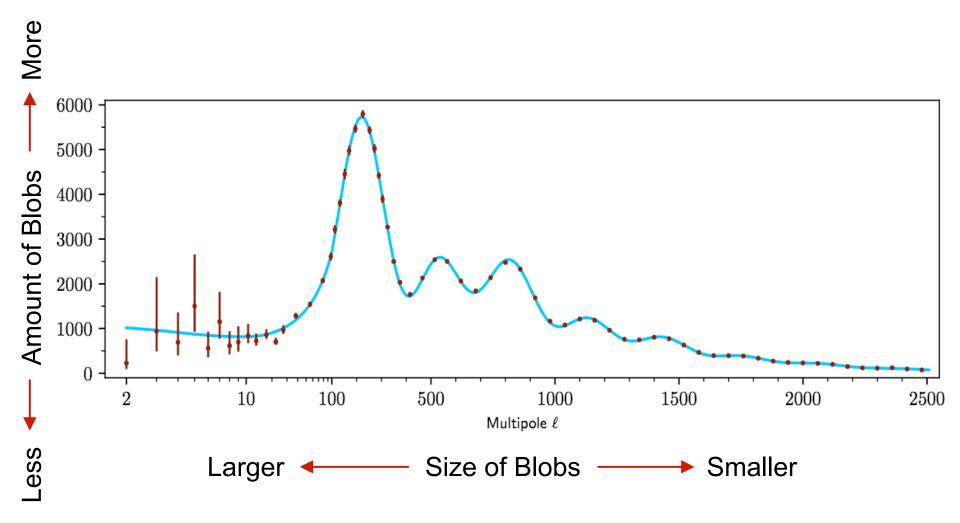

⇒ acceptance of the "HOT BIG BANG"

### **Cosmic Microwave Background Surface of Last Scattering**

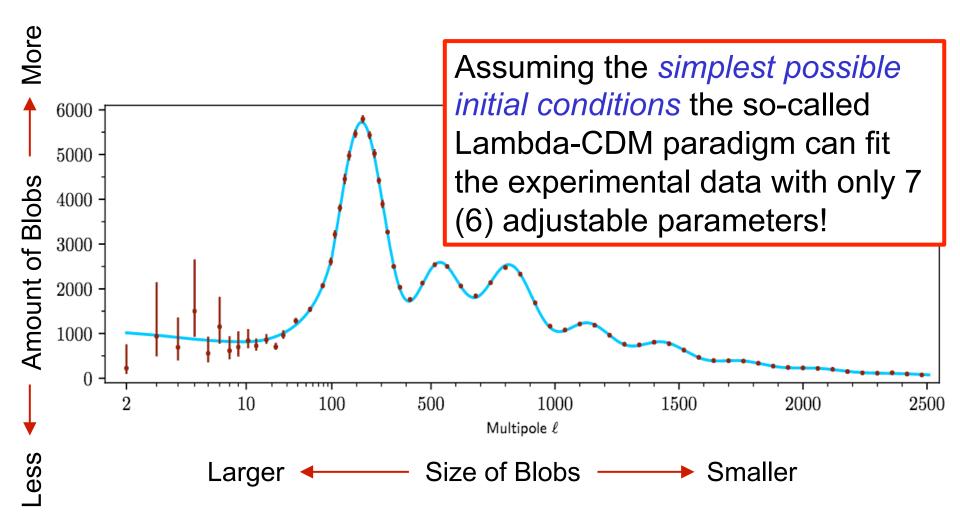

CMB temperature map is a sample of the density structure on a spherical shell cut through the 380,000 year old Universe Perturbations were one part in 10,000 at that time – and Gaussian!

## Power Spectrum (Blob size histogram)

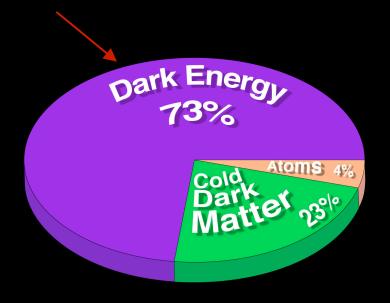

## Power Spectrum (Blob size histogram)

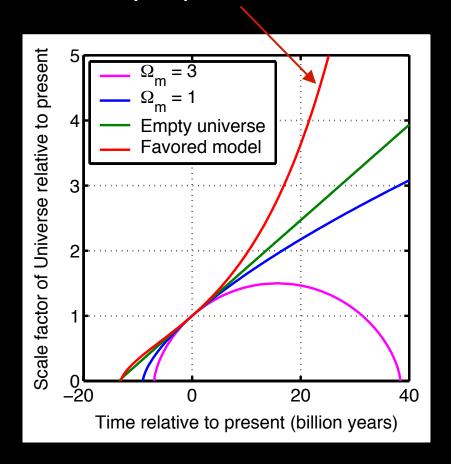

## **Triumphant/Embarrassing Contemporary Cosmology**

CMB and other data fits GR based LCDM model *beautifully* – but it demands that 96% of the Universe is invisible to us

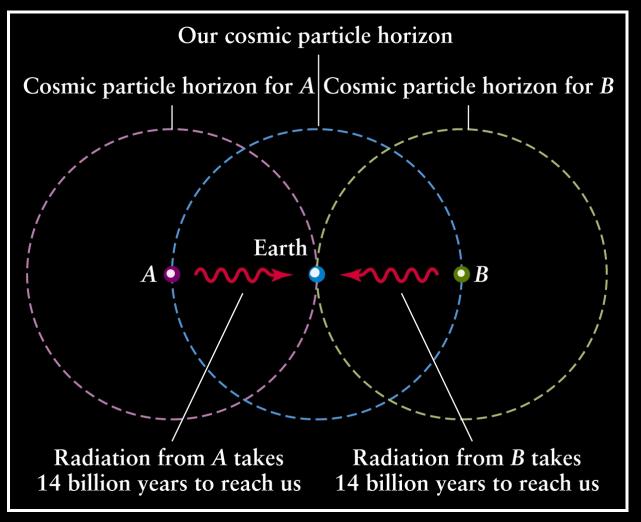

And it implies that the future is runaway expansion...

Also it doesn't explain horizon/flatness etc...

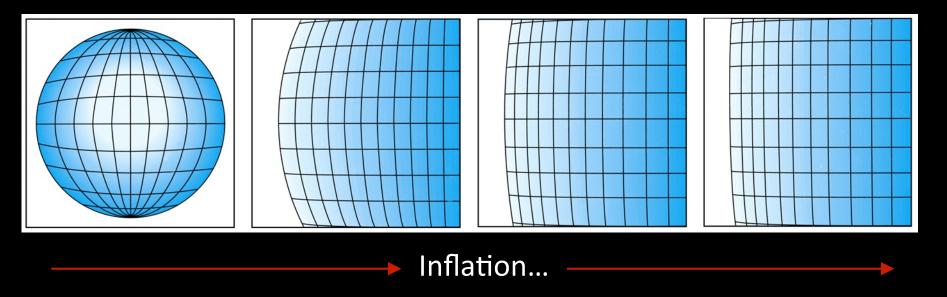

## **The Horizon Problem**

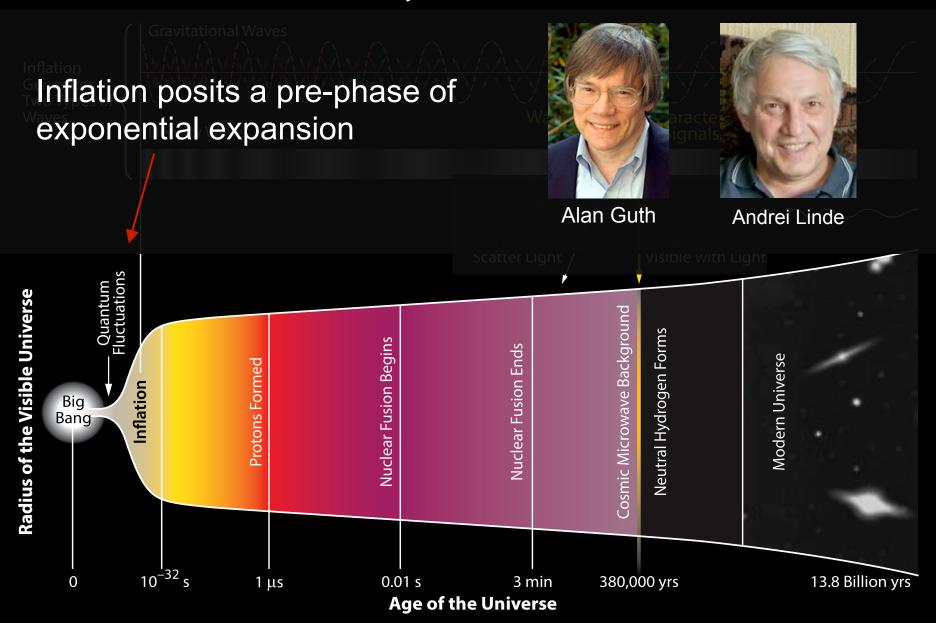

How did points A and B "know" to be at the same temperature in the distant past when they had never been in causal contact?

(They still aren't today!)

## Inflation solves the Flatness Problem

If you take some curved space and blow it up enough pretty soon it is no longer curved on a local scale – where "local scale" here means our entire observable Universe!

#### What Does Inflation Do For Us?

Solves the horizon problem: Why is the CMB nearly uniform? How do apparently causally disconnected regions of space get set to the same temperature?

A volume much larger than our entire observable universe today was once a causally connected sub atomic speck.

Solves the flatness problem: Why is the net spatial curvature so close to zero?

Any initial spatial curvature is diluted away to undetectabilty by the hyper expansion.

Explains the initial perturbations: Why Gaussian with close to flat power law spectrum?  $(n_s \approx 1)$ 

Equal amounts of perturbations are injected by quantum fluctuations at each step in the exponential expansion.

Solves the monopole problem: Why do we not observe magnetic monopoles in the Universe today?

Monopoles are diluted away to undetectability.

#### What Does Inflation Do For Us?

Solves the horizon problem: Why is the CMB nearly uniform? How do apparently causally disconnected regions of space get set to the same temperature?

Solves the flatness problem: Why is the net spatial curvature so close to zero?

Explains the initial perturbations: Why Gaussian with close to flat power law spectrum?  $(n_s \approx 1)$ 

Solves the monopole problem: Why do we not observe magnetic monopoles in the Universe today?

These simplest possible initial conditions are the starting point of the beautiful simulations of the development of large scale structure which Durham is famous for

tne nyper expansion.

Equal amounts of perturbations are injected by quantum fluctuations at each step in the exponential expansion.

Monopoles are diluted away to undetectability.

#### Inflation is controversial

## CMB Polarization, B-modes and r

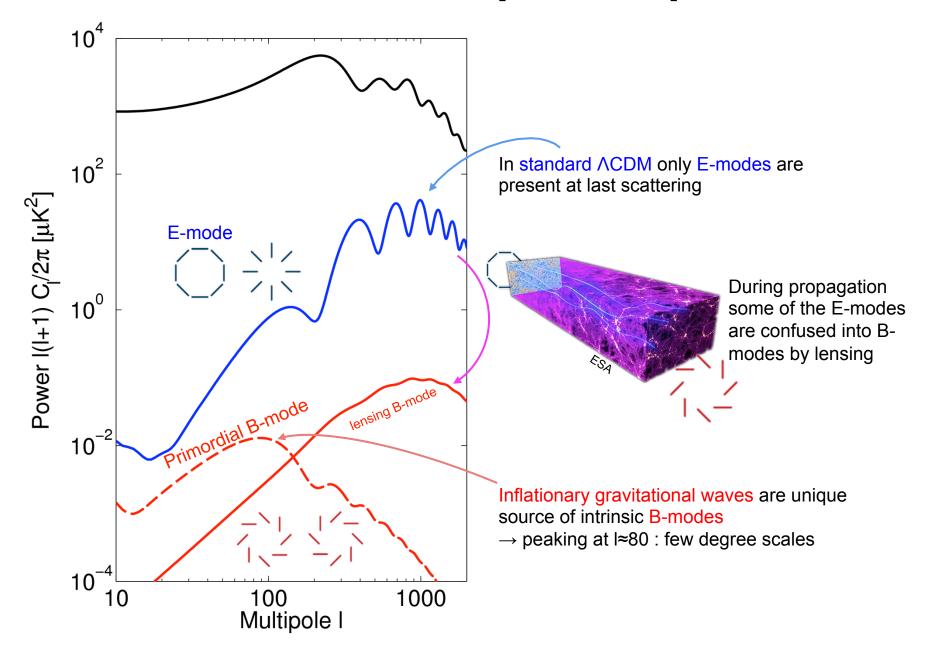

- The CMB is partially polarized (due to local radiation quadrupoles at last scattering)
- Any polarization pattern can be decomposed into E-modes (gradient modes) and B-modes (curl modes)
- ➤ Basic LCDM makes only E-modes at last scattering although lensing deflections in flight produce a bit of a B-mode
- Primordial gravitational waves produce both E-modes and B-modes but best to look for the B-modes since most distinct there
- ➤ Theory gives us a good template shape for the gravitational wave signal but it does *not* tell us the amplitude
- $\rightarrow$  The amplitude is parameterized by a single number r
- A wide range of inflation theories exist the simplest are already ruled out – more complex ones can produce r which is undetectably small
- $\succ$  The experimental mission is to obtain the best possible sensitivity to r
- ➤ If we can detect r we determine the energy scale of inflation if not we can rule out additional inflationary models

## CMB Polarization, B-modes and r

- The CMB is partially polarized (due to local radiation quadrupoles at last scattering)
- Any polarization pattern can be decomposed into E-modes (gradient modes) and B-modes (curl modes)
- ➤ Basic LCDM makes only E-modes at last scattering although lensing deflections in flight produce a bit of a B-mode
- Primordial gravitational waves produce both E-modes and B-modes but best to look for the B-modes since most distinct there
- ➤ Theory gives us a good template shape for the gravitational wave signal but it does *not* tell us the amplitude
- $\rightarrow$  The amplitude is parameterized by a single number r
- ➤ A wide range of inflation theoric ruled out more complex ones small Warning: It's a bit like the search for proton decay a well motivated physics target to look
- > The experimental mission is to
- If we can detect r we determine we can rule out additional inflat

Warning: It's a bit like the search for proton decay — a well motivated physics target to look for, but theories can be adjusted to make the amplitude arbitrarily small...

## **CMB** Polarization power spectra

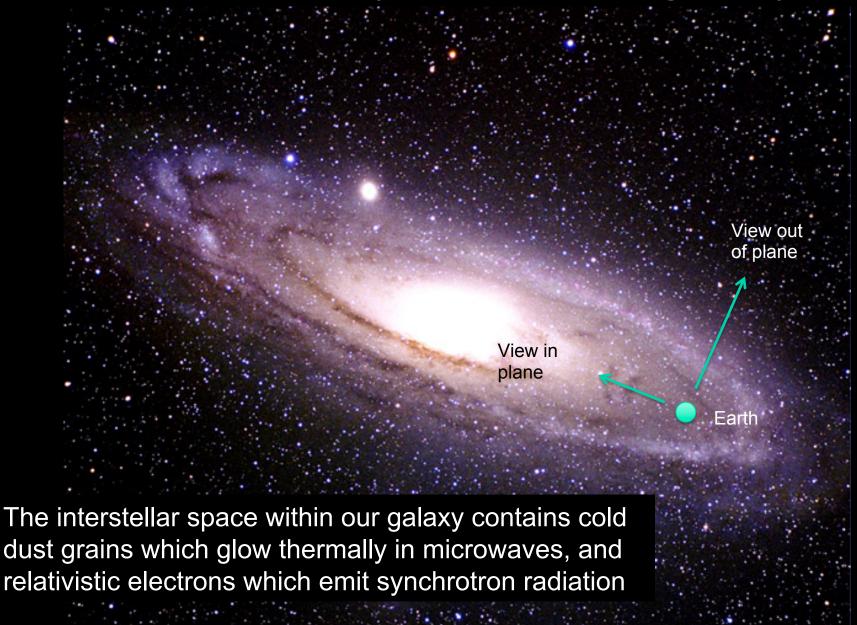

# BICEP/Keck Basic Experimental Strategy

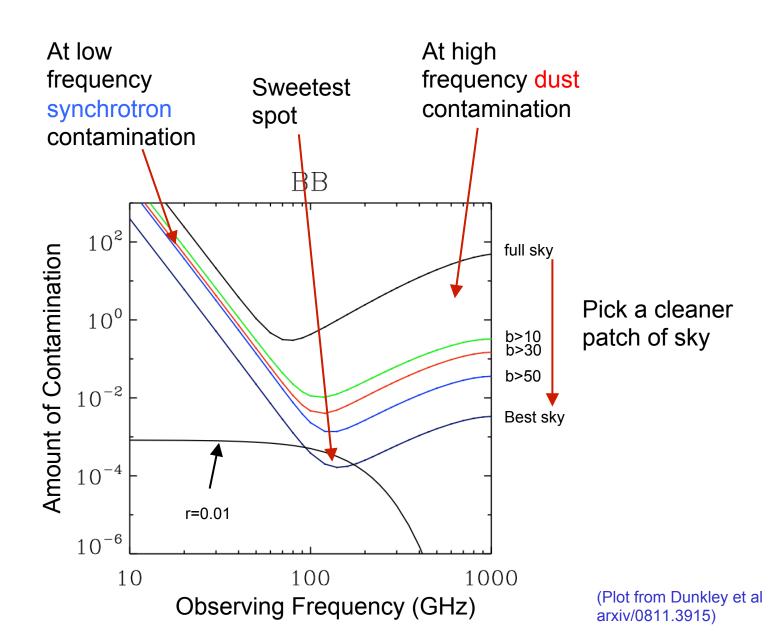

- → Small aperture telescopes (cheap, fast, low systematics)
- → Target the 2 degree peak of the PGW B-mode
- → Integrate continuously from South Pole
- → Observe order 1% patch of sky (smaller is actually better!)
- → Scan and pair difference modulation

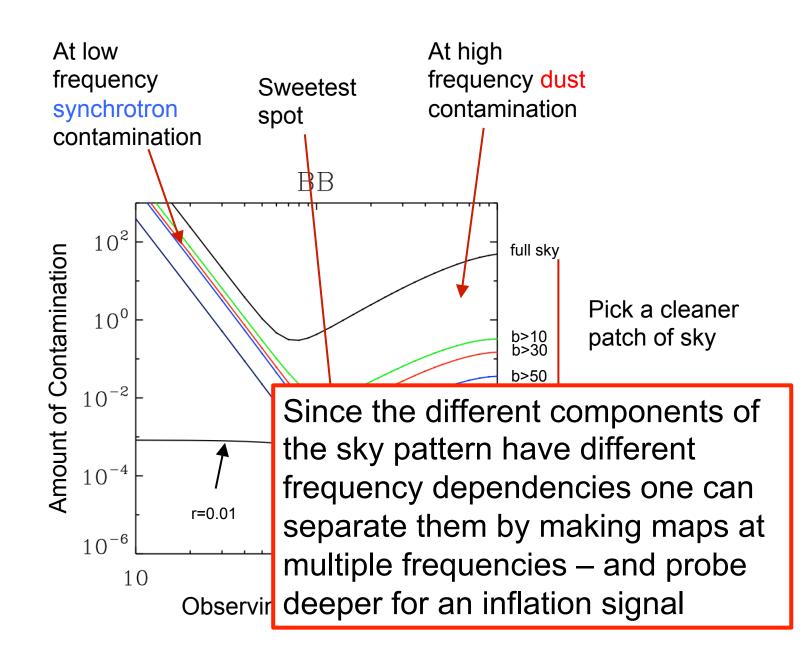

# Unfortunately we are in a galaxy

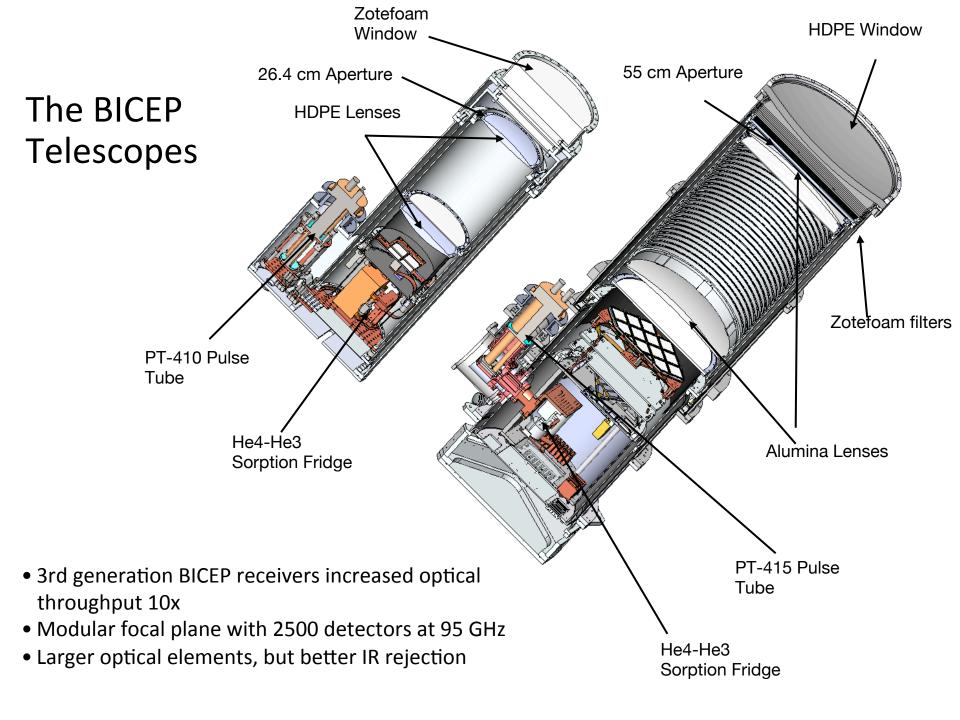

## Polarized Foreground Contamination from Our Galaxy

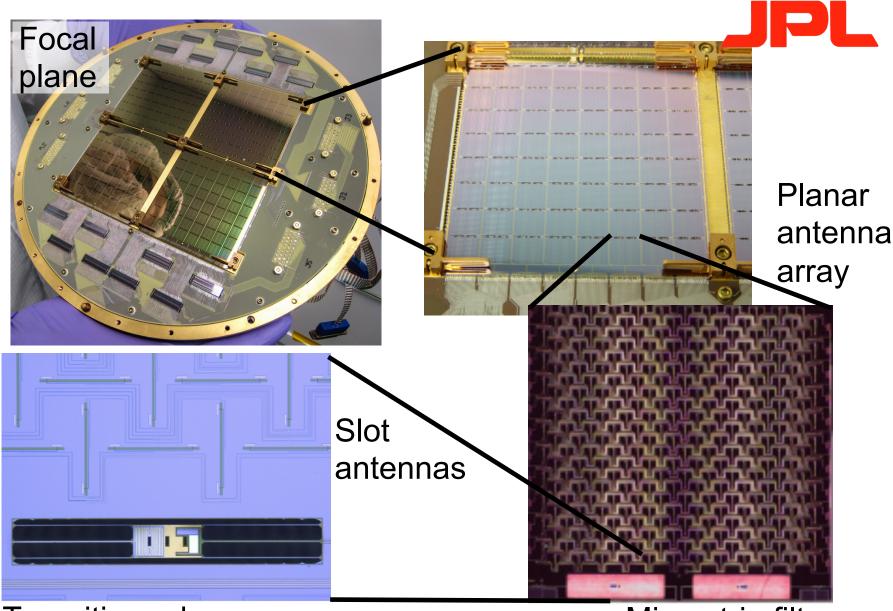

## Polarized Foreground Contamination from Our Galaxy

## Mass-produced Superconducting Detectors

Transition edge sensor

Microstrip filters

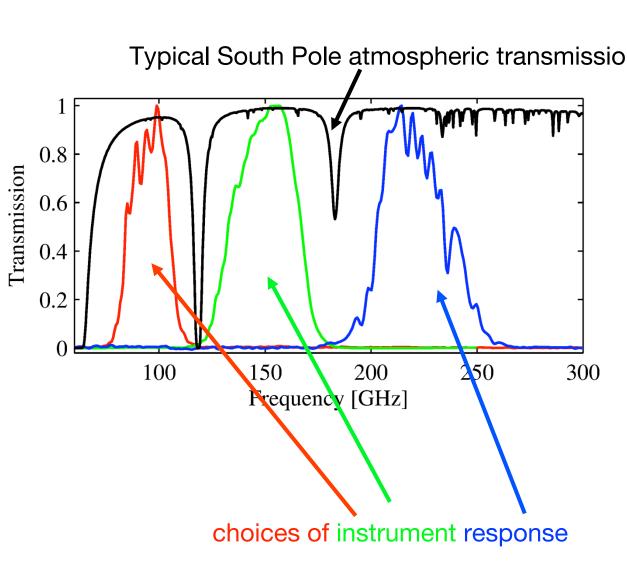

## **BICEP/Keck Band Passes**

The dry South Pole atmosphere provides excellent observing conditions most of the year.

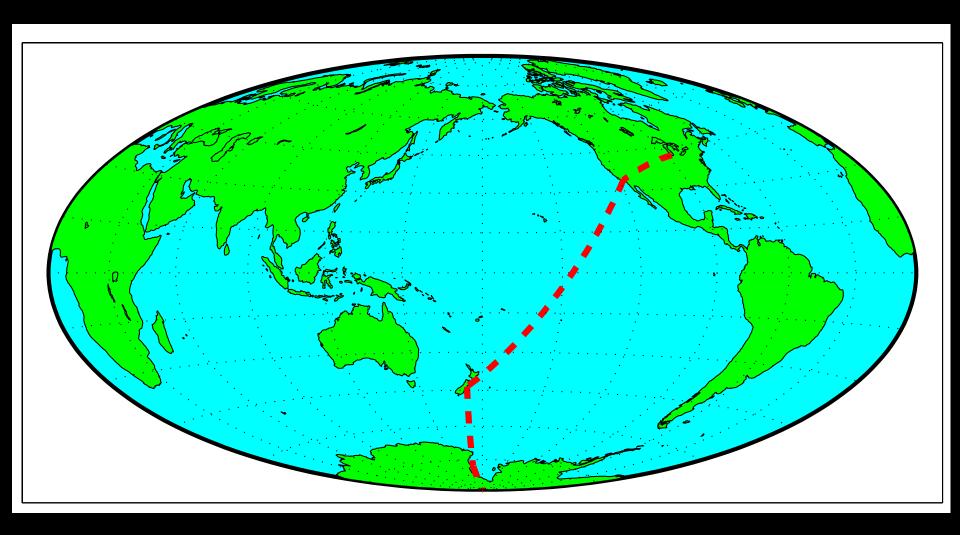

The approx. 30% fractional bandpasses fit within atmospheric transmission windows straddled by oxygen and water lines.

In these windows, the atmosphere is quite transparent to microwaves.

The detector passbands are defined by a filter printed directly onto the focal plane wafers.

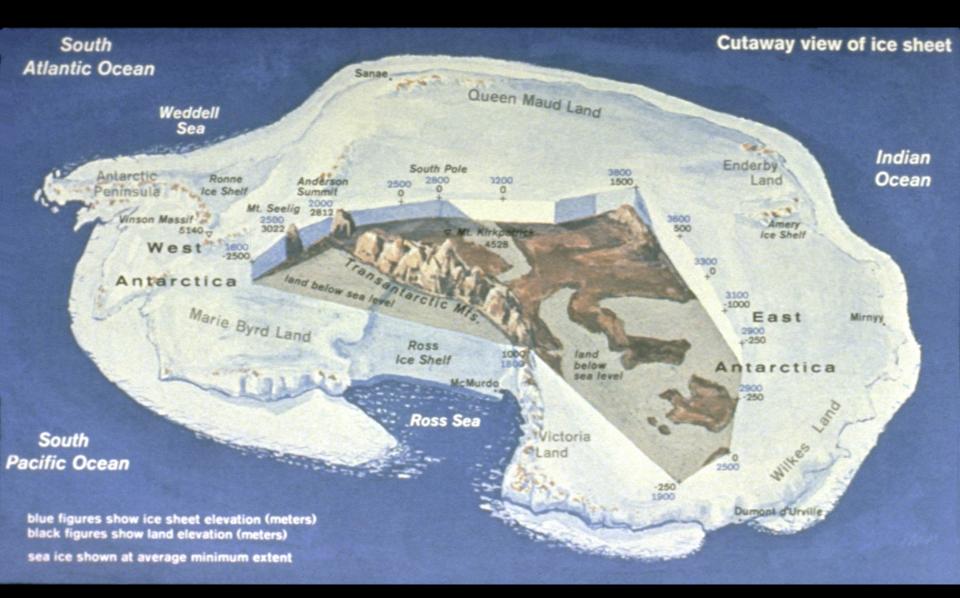

## **Journey to the South Pole**

Minneapolis -> California -> New Zealand -> McMurdo -> South Pole

## **Antarctic Continent**

Larger than the US – Ice sheet 3000 meters thick!

## **Christchurch New Zealand – Clothing Warehouse**

# Big Program!

# **Arrival in Antarctica**

# McMurdo – base on the coast

#### On to the Pole – over the Transantarctic Mountains

## **Unloading at Pole**

#### **The Actual South Pole**

# **Nothing Out There!**

#### Why do this at the Pole?

- High and dry excellent atmospheric transmission
- On Earth's rotational axis One day/night cycle per year
  - Long night makes for great quality data
- Good support infrastructure power, cargo, data comm
- Food and accommodation provided
- Even Tuesday night bingo...

# -5 Degrees on sky

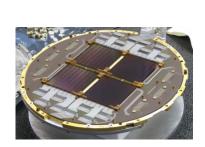

**BICEP2** 

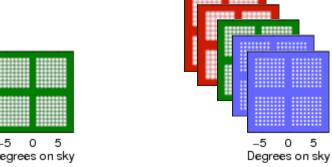

(2010-2012)

Stage 2 **Keck Array** (2012-2019)

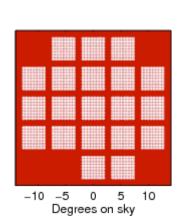

**BICEP3** (2016-present)

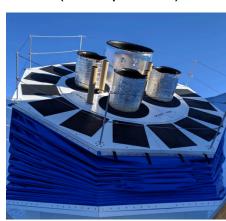

Stage 3

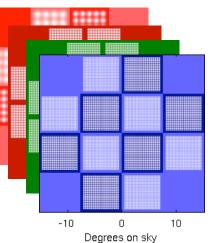

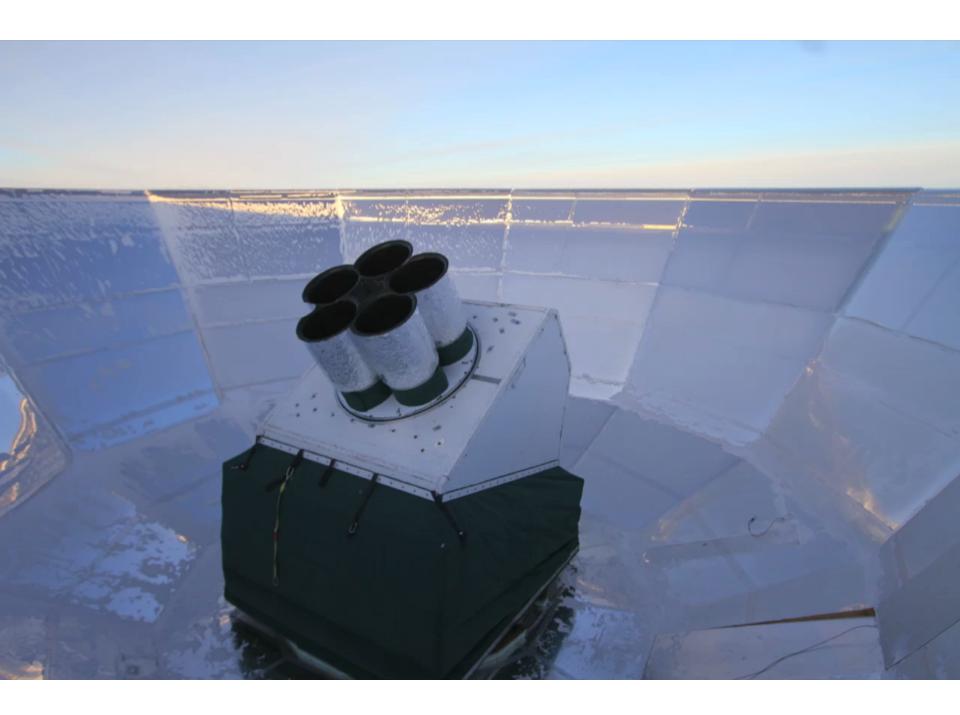

**BICEP Array** (2020-present)

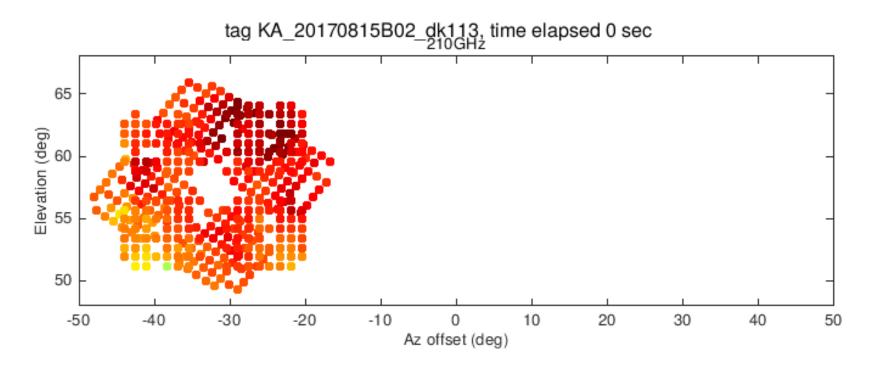

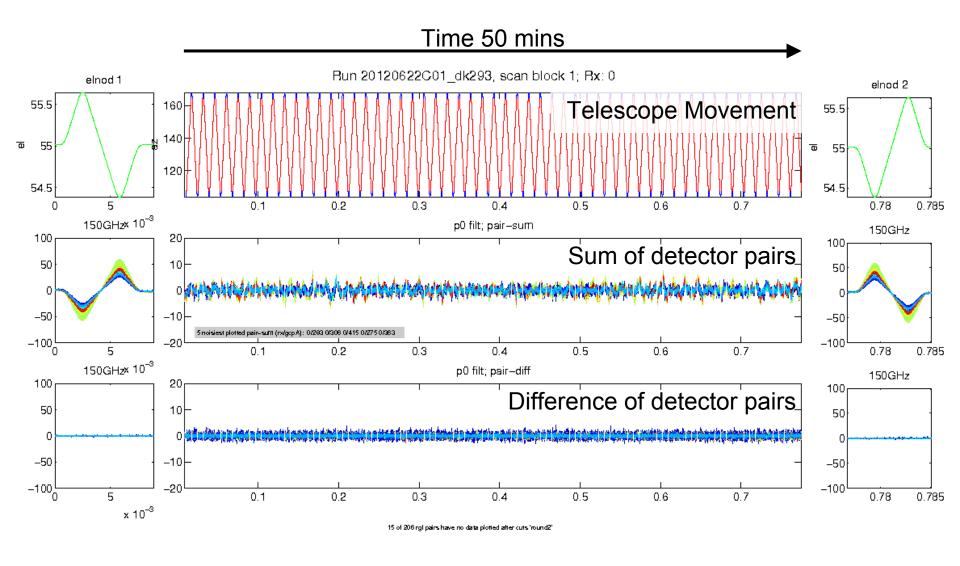

# Bolometer readouts as the telescope scans back and forth

The physical temperature of the detectors tracks the intensity of the incoming radiation from little "spots" on the sky.

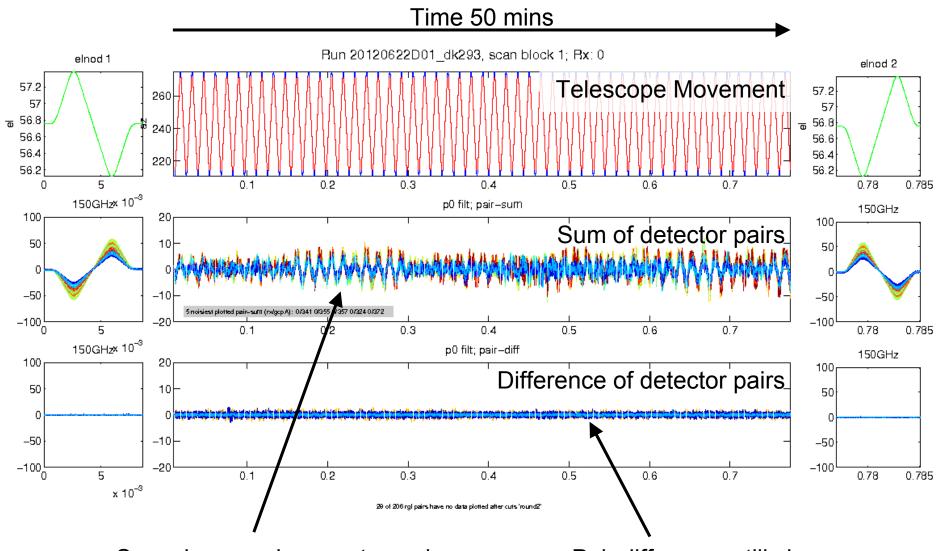

This plot is unpolarized – we are seeing "clouds" blowing across the scan region.

#### Raw Data - Excellent Weather

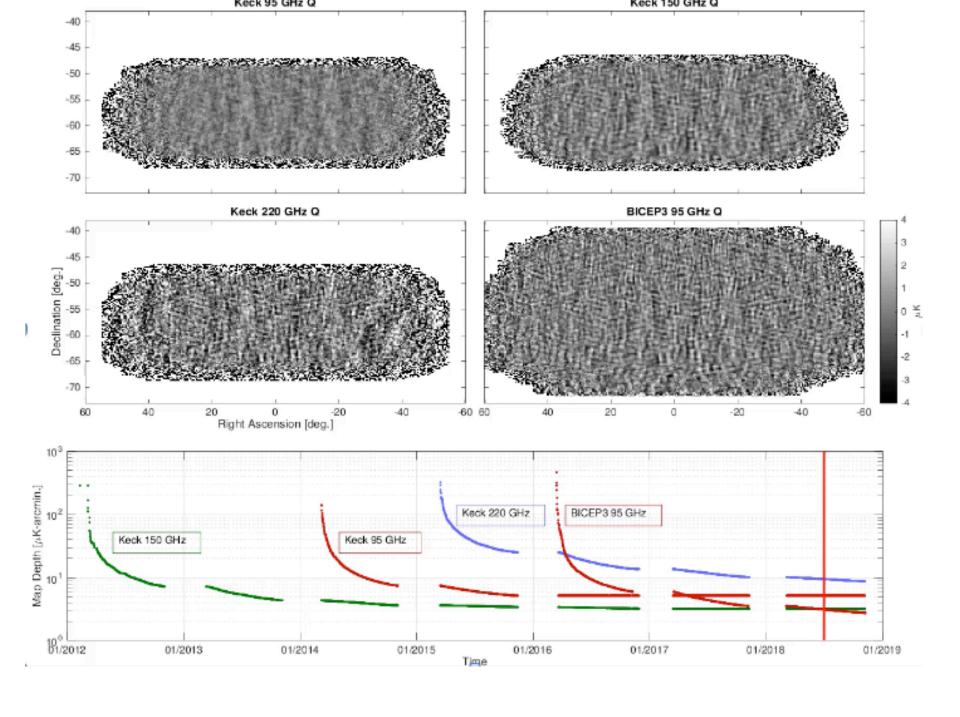

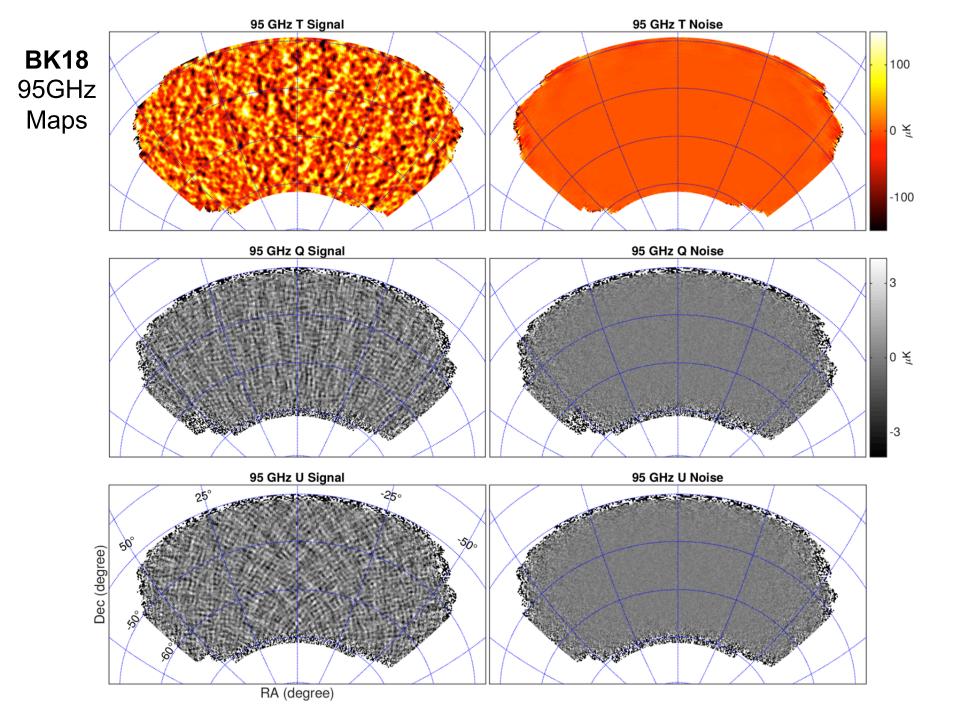

- Cover the whole field in ~40 such scansets > Scanning modulates the CMB then start over at new boresight rotation
  - signal to freqs < 4 Hz

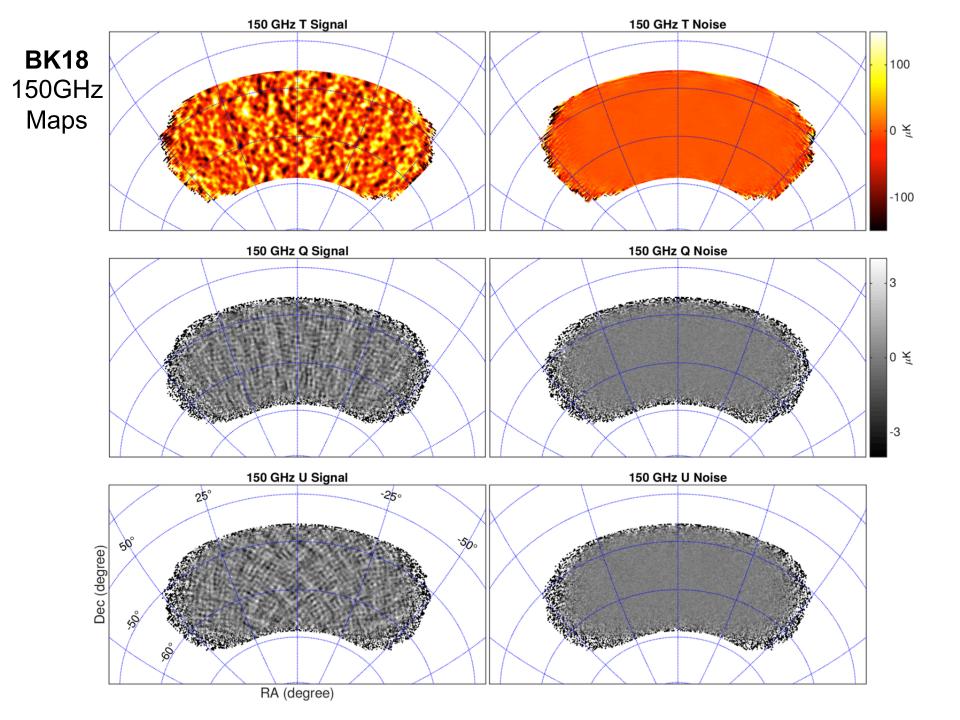

#### Raw Data - Worse Weather

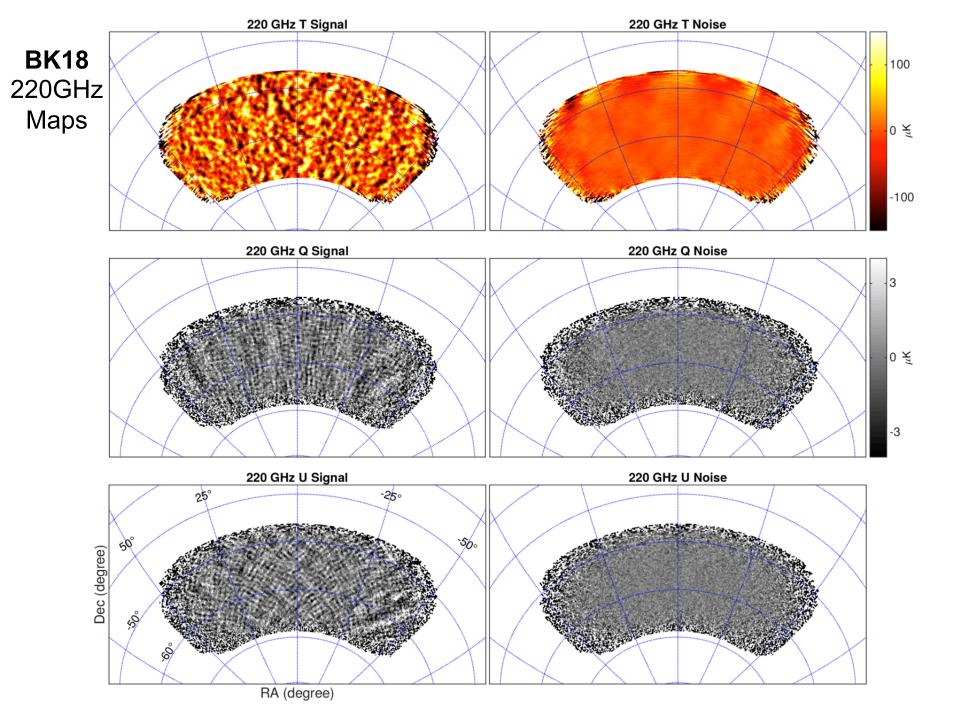

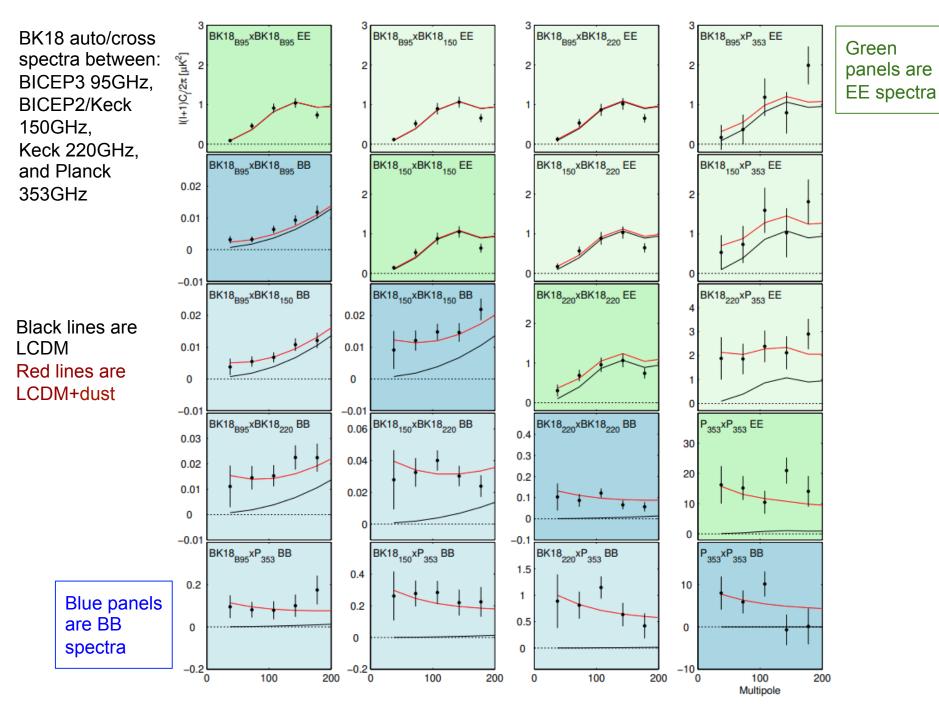

- ➤ Scanning over lumpy atmosphere → "clouds"
- → Pair difference still clean
   → atmosphere is unpolarized

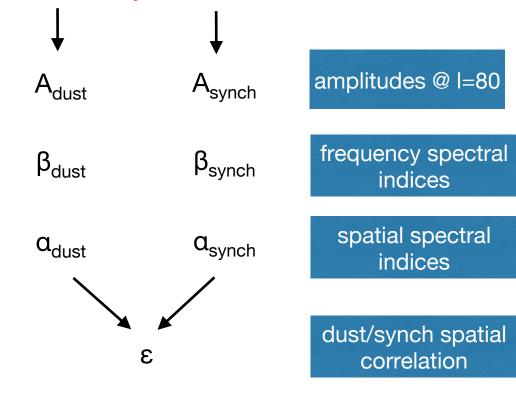

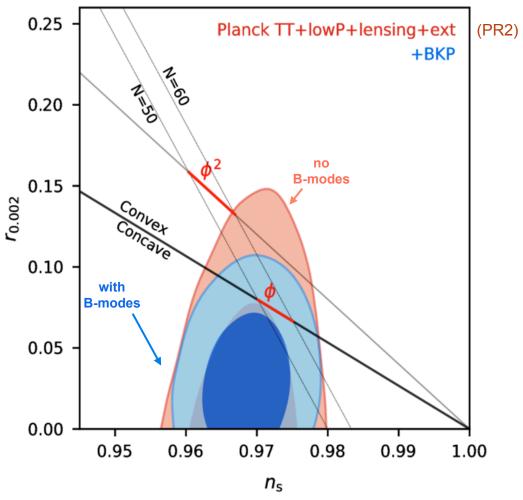

#### Multicomponent parametric likelihood analysis

Take the joint likelihood of all the spectra simultaneously vs. model for BB that is the  $\Lambda$ CDM lensing expectation + 7 parameter foreground model + r

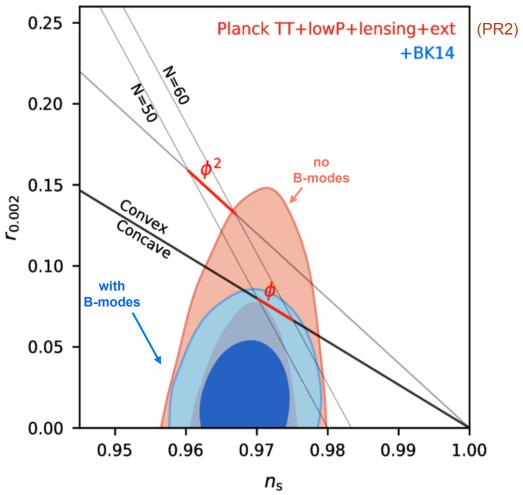

foreground model = dust + synchrotron

 $r_{.05} < 0.09$ 

**BKP** arxiv/1502.00612

 $r_{.05} < 0.07$ 

**BK14** arxiv/1510.09217

 $r_{.05} < 0.06$  BK15 arxiv/1810.05216

 $r_{.05} < 0.035$  BK18 arxiv/2110.00483

#### Per bandpower CMB component extraction

#### What limits BK18?

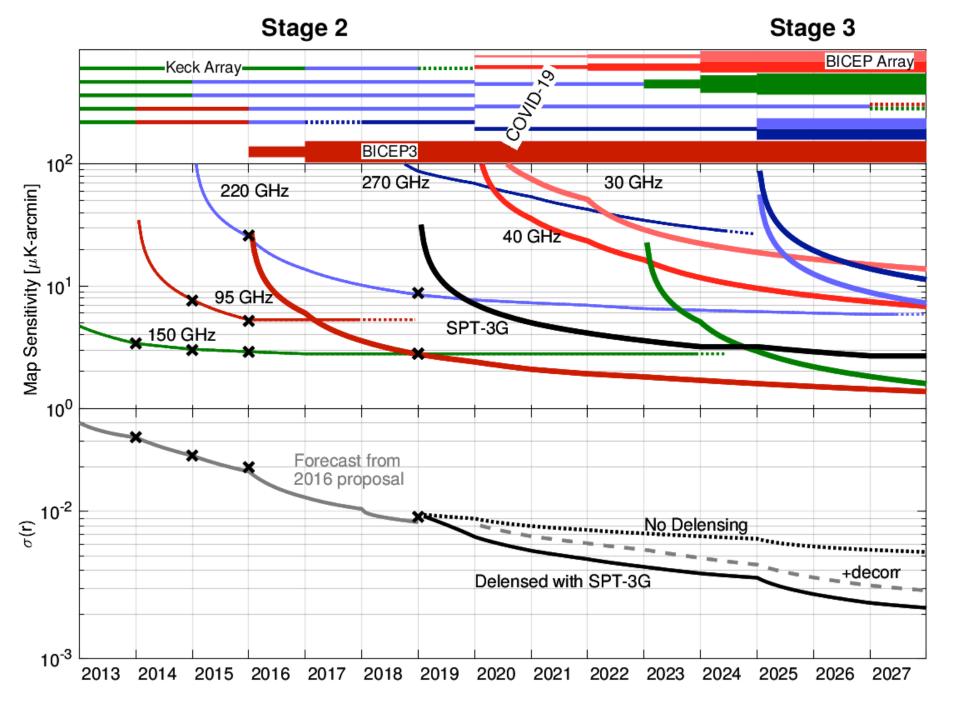

- **A** BK18 mainline simulations with dust and lensing give  $\sigma(r)=0.009$
- Running without foreground parameters on simulations where the dust amplitude is set to zero gives  $\sigma(r)=0.007$

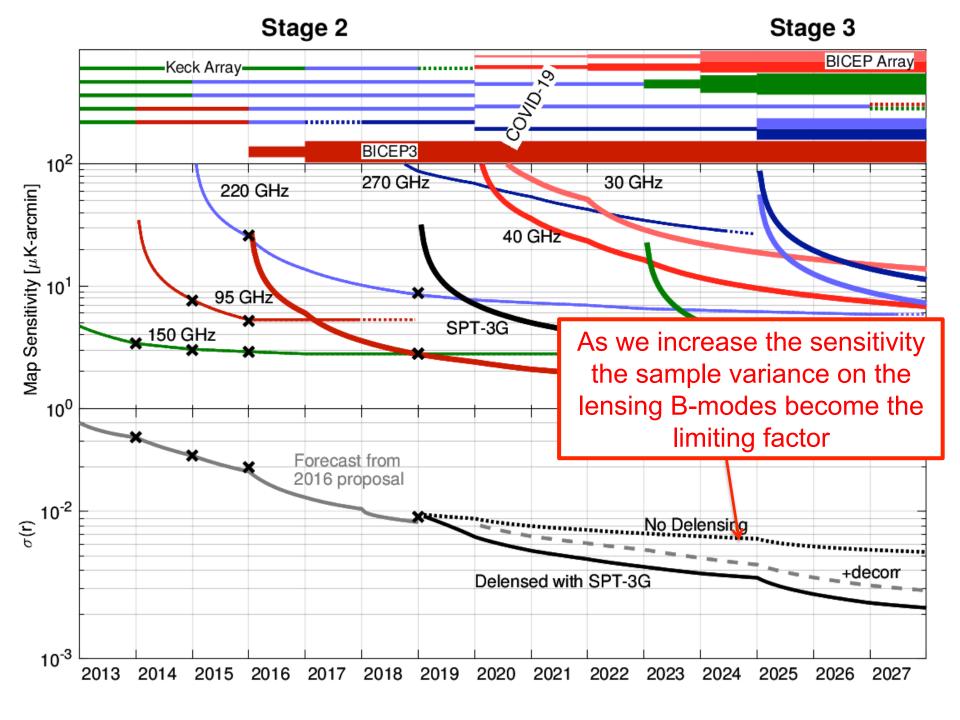

The above is as it should be - we have correctly tuned the relative sensitivity of the 95/150/220 bands such that we don't suffer much penalty due to the presence of foregrounds.

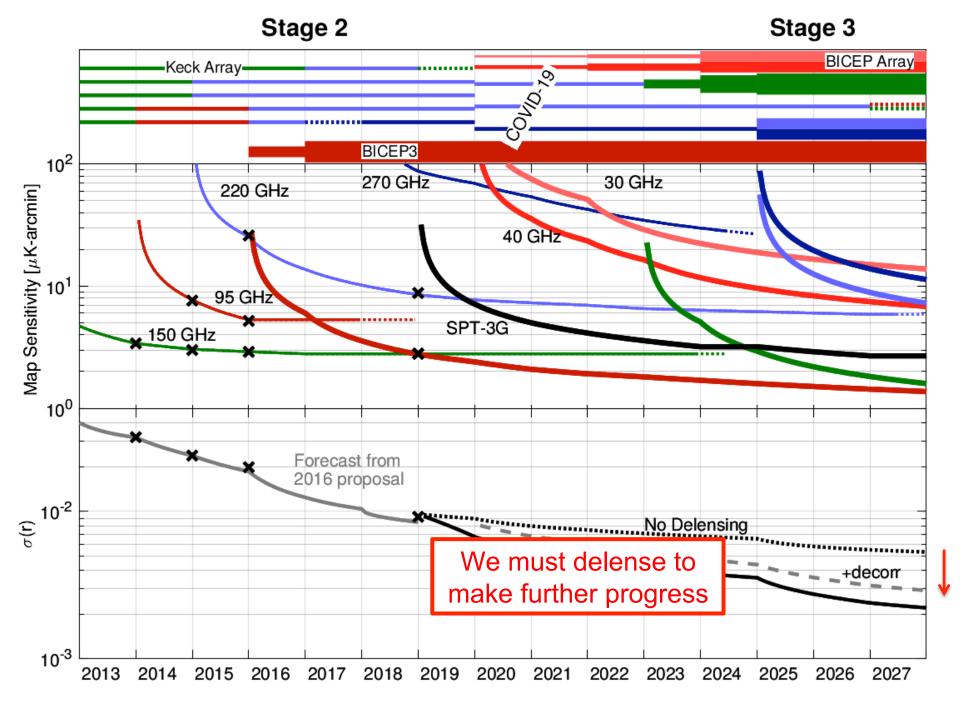

Running on simulations which contain no lensing gives  $\sigma(r)=0.004$ 

The sample variance of the achromatic lensing foreground is a major limiting factor - we need delensing via high resolution measurements.

Running without foreground parameters on simulations which have neither dust or lensing gives  $\sigma(r)=0.002$ 

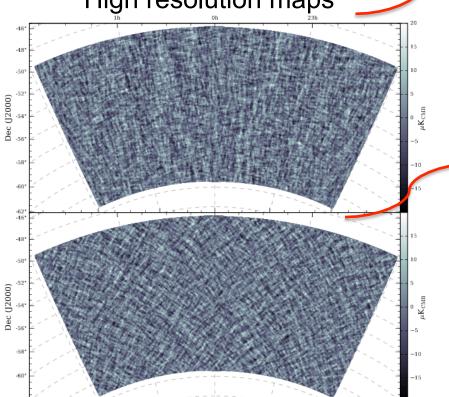

# Delensing with SPT-3G data

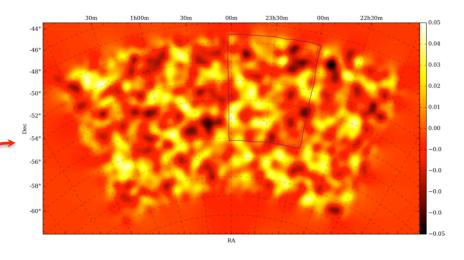

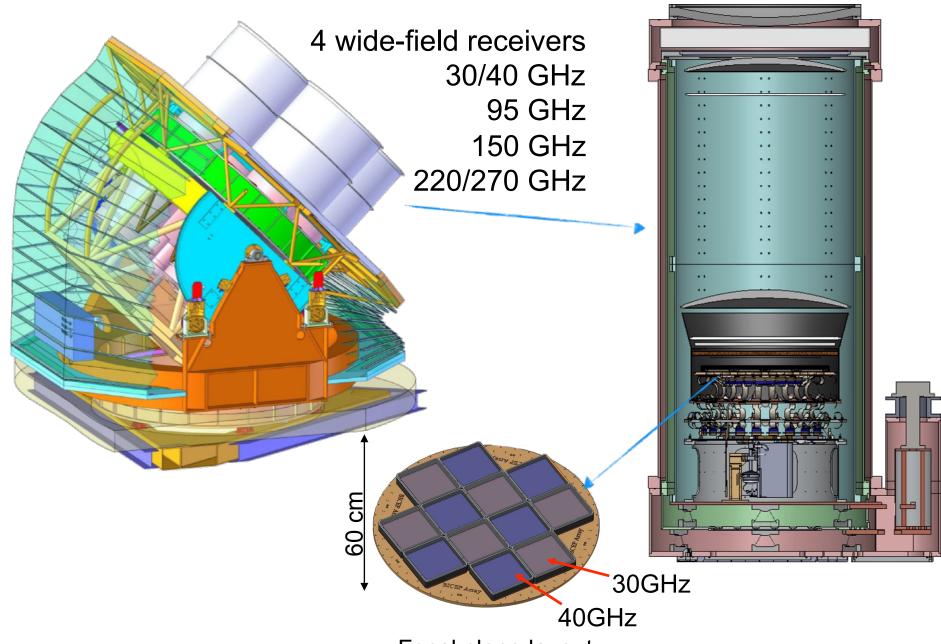

RA ([2000)

Can be used to reconstruct the lensing deflection map...

...which can then be used to calculate the lensing signal enabling a deeper search for inflationary gravitational waves

#### **Latest Generation Experiment "BICEP Array"**

Focal plane layout

## BICEP Array 2019-20 initial deployment

Three-month window during the Antarctic summer to perform:

- Keck Array demolition
- BA mount installation
- BA1 receiver assembly
- Full system integration

60,000 lbs of cargo, equivalent to 3 dedicated LC-130 Hercules flights to the South Pole.

30+ personnel:

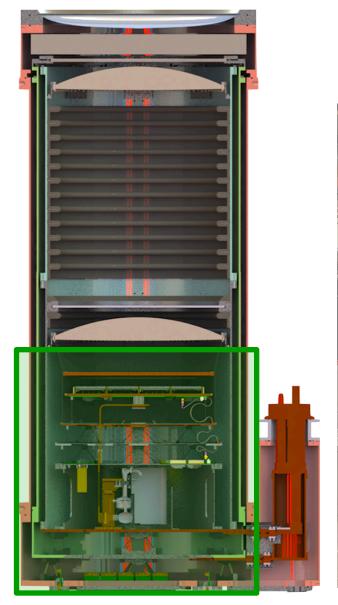

- 2/3 scientists
- 1/3 contractors

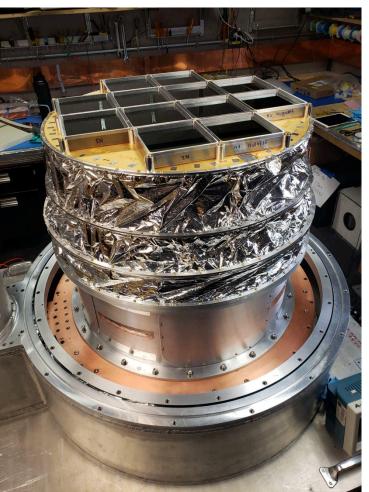

#### 2020-onwards BA1 (30/40GHz) Instrument Operating

#### **Camera insert**

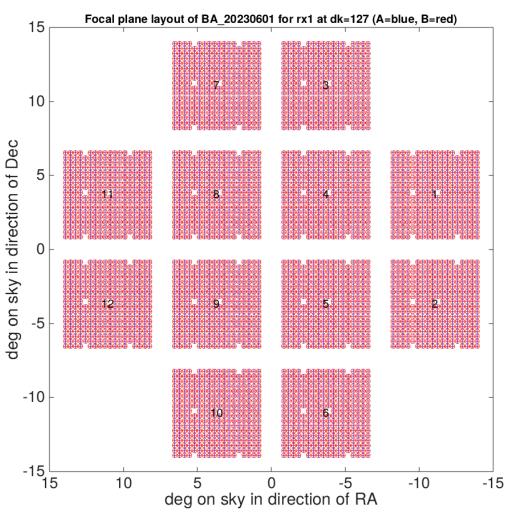

192/300 TES detectors at 30/40 GHz.

Integrated in 12 shielded modules, each with a low-pass mesh filters.

Time-Domain multiplexed readout.

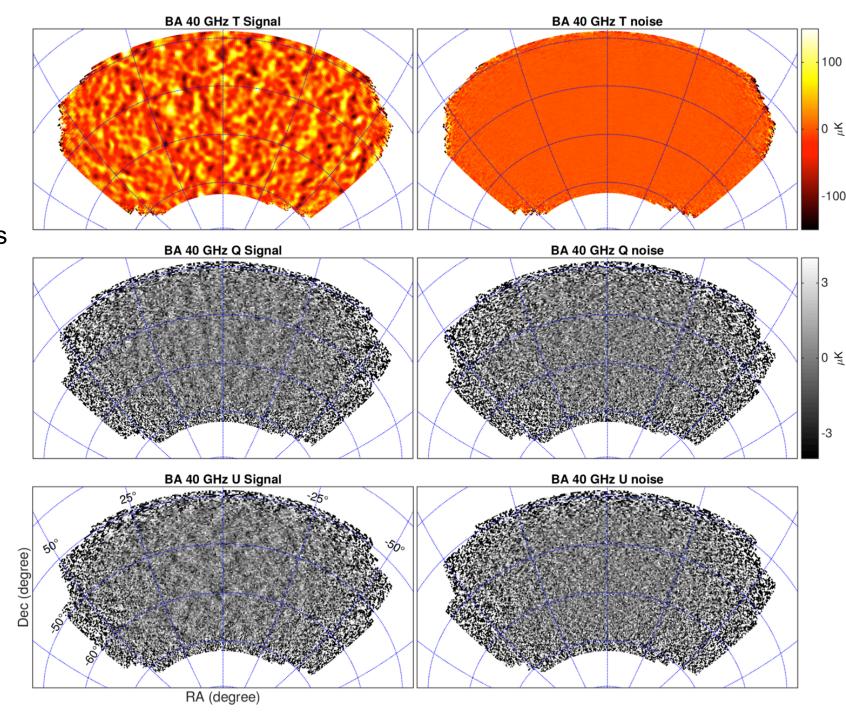

### 2023-onwards BA2 (150GHz) Instrument Operating

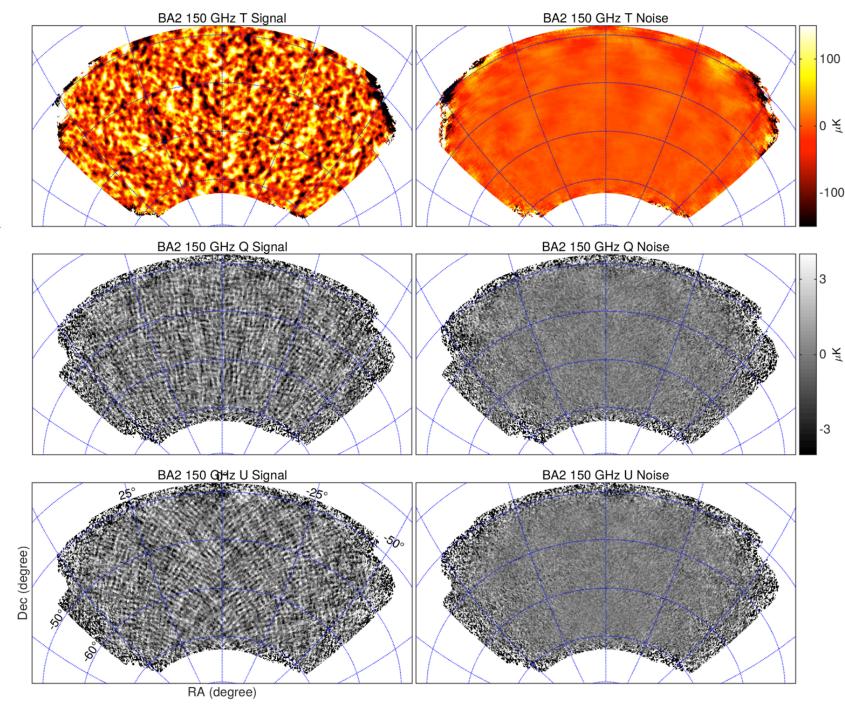

**BA1** 40GHz Maps

Prelim analysis of 3 years of data

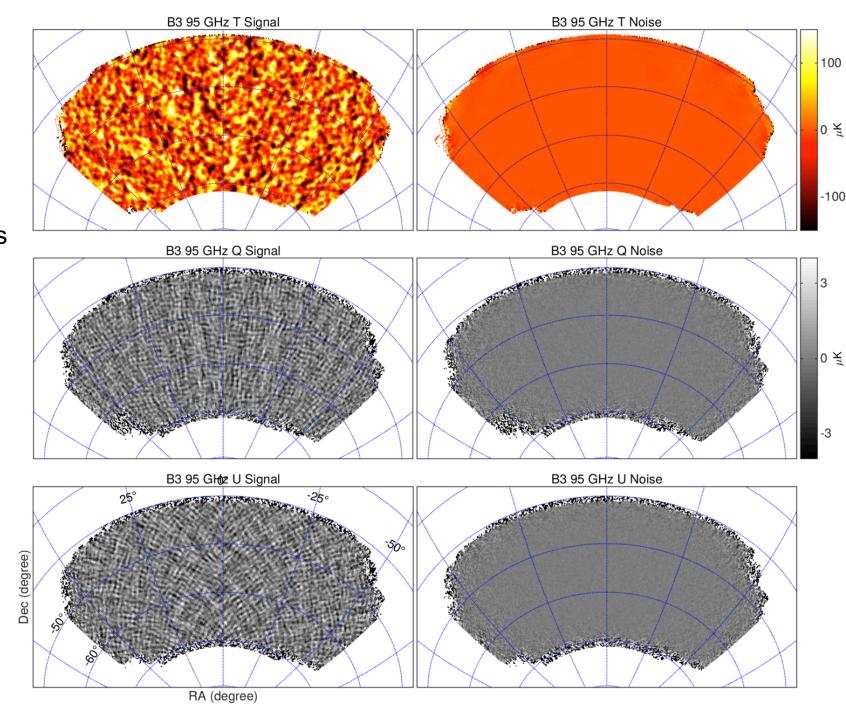

**BA2** 150GHz Maps

Prelim analysis of 1 year of data

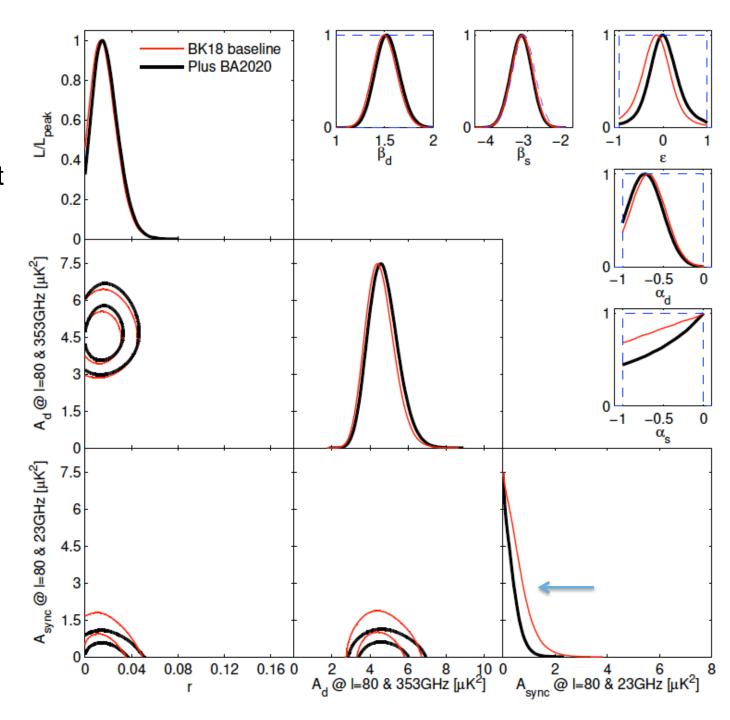

BICEP3 95GHz Maps

Prelim analysis of 8 years of data

Prelim analysis adding first year 30/40GHz — still does not detect synchrotron — just pushes the upper limit further down

## **Summary**

- The CMB tells us in exquisite detail the state which the universe was in when it made the transition from opaque plasma to neutral gas.
- ➤ With this knowledge we can extrapolate forward/backward in time LCDM it all works great! But does not explain what set the initial conditions. (They were simple!)
- ➤ The theory of "Inflation" explains our entire observable Universe came from a single sub-atomic spec in an ultra brief burst of hyper expansion
  - ➤ If this actually happened it will have injected a background of gravitational waves
    - ➤ We may be able to detect the imprint of these by measuring the polarization pattern of the Cosmic Microwave Background if we can build a sensitive enough telescope
      - $\triangleright$ BICEP/Keck sets the world's best upper limit to date (r < 0.036) ruling out multiple previously popular classes of inflationary models (monomial and natural)
        - ➤ And the search goes on with bigger and better experiments... (BICEP Array & SO projecting ~3x better, CMB-S4 6x better than that)

## **Backup Slides**

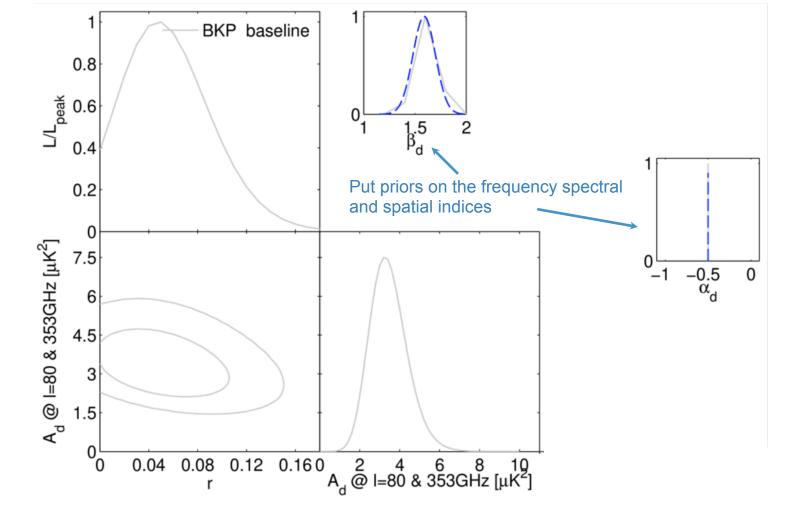

## Stage IV CMB experiment: CMB-S4

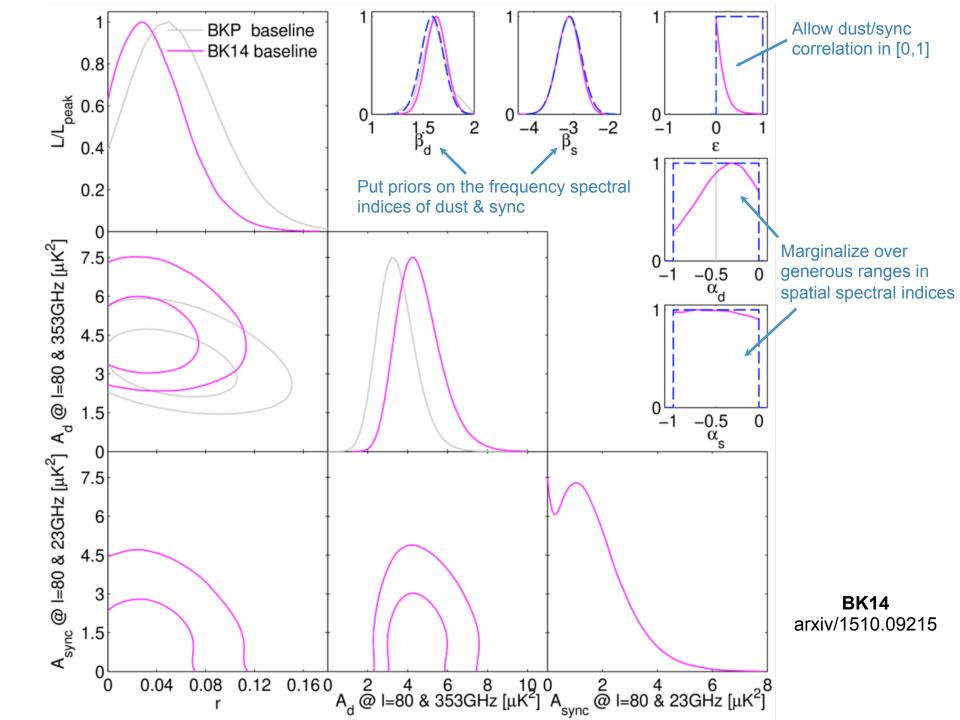

- CMB-S4: a next generation ground-based program building on CMB stage
   2 & 3 projects to pursue <u>inflation</u>, <u>neutrino properties</u>, <u>dark energy</u> and new discoveries.
- Targeting to deploy O(500,000) detectors spanning 30 300 GHz using multiple telescopes and sites to map most of the sky to provide sensitivity to cross critical science thresholds.
- Multi-agency effort (DOE & NSF). Complementary with balloon and space-based instruments.
- Broad participation of the US CMB community, including the existing NSF CMB groups, DOE National Labs and the High Energy Physics community.
- U.S. led program; international partnerships expected.

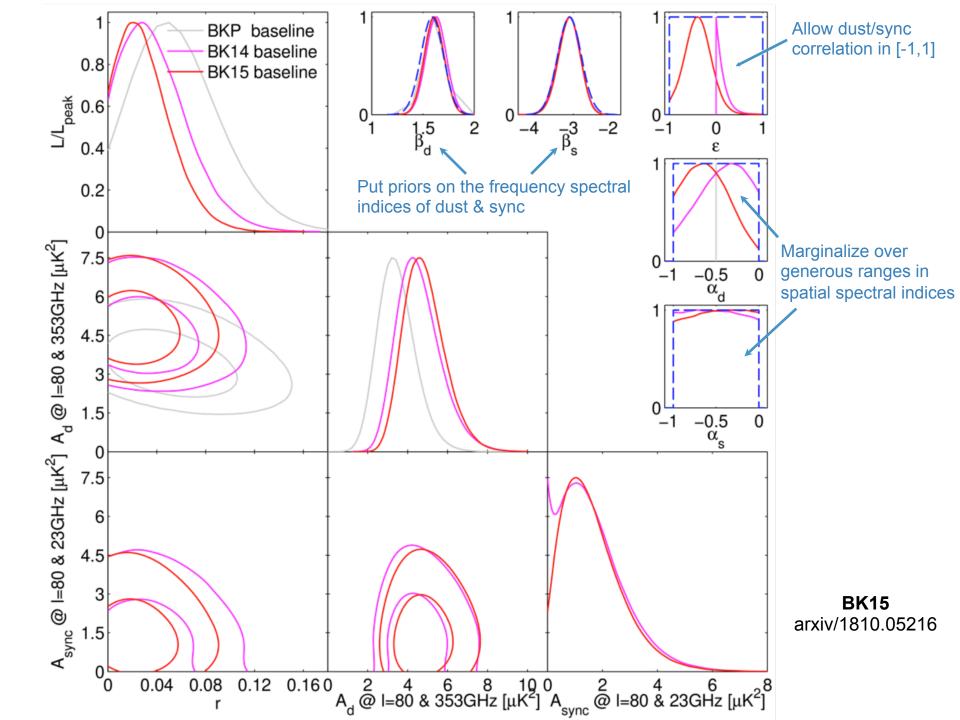

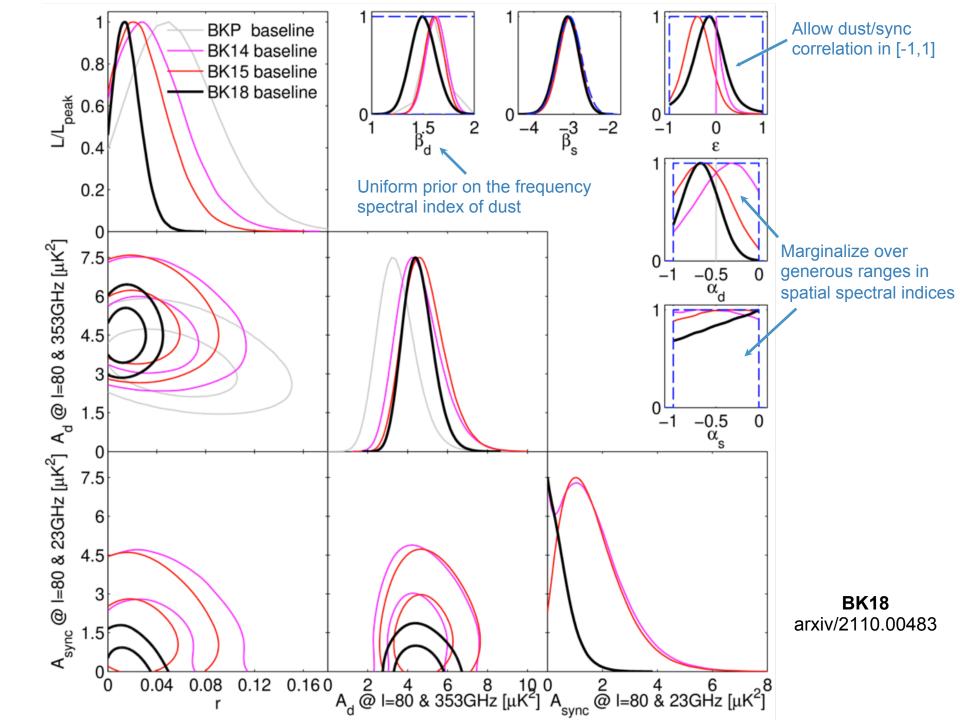

A science driven program combining the deep CMB experience of the university groups with the expertise and resources at the national labs.

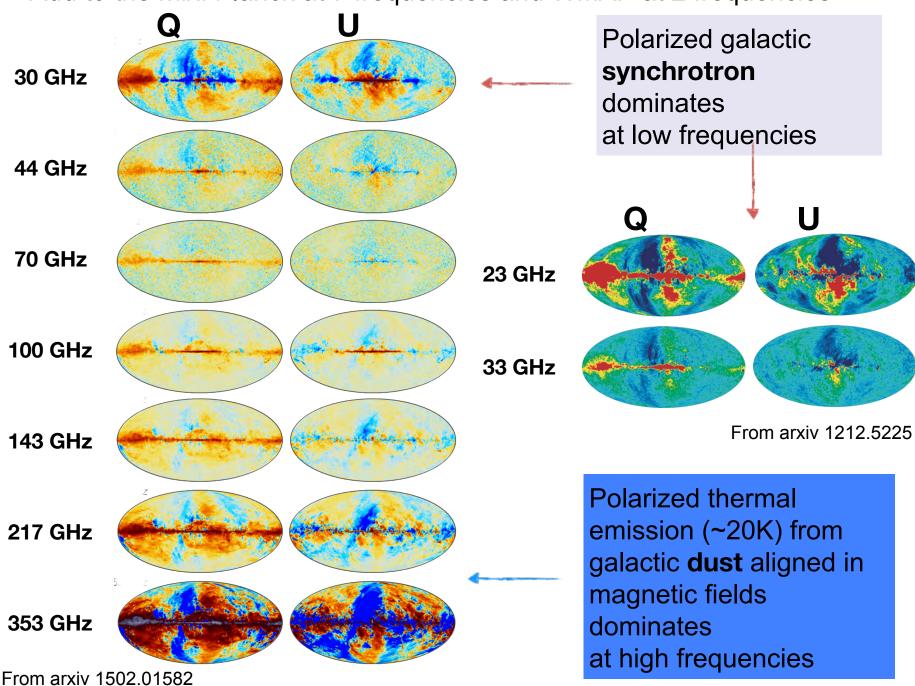

**BKP** arxiv/1502.00612

Add to the mix: Planck at 7 frequencies and WMAP at 2 frequencies

## **Dust/Sync Spatial Power Laws?**

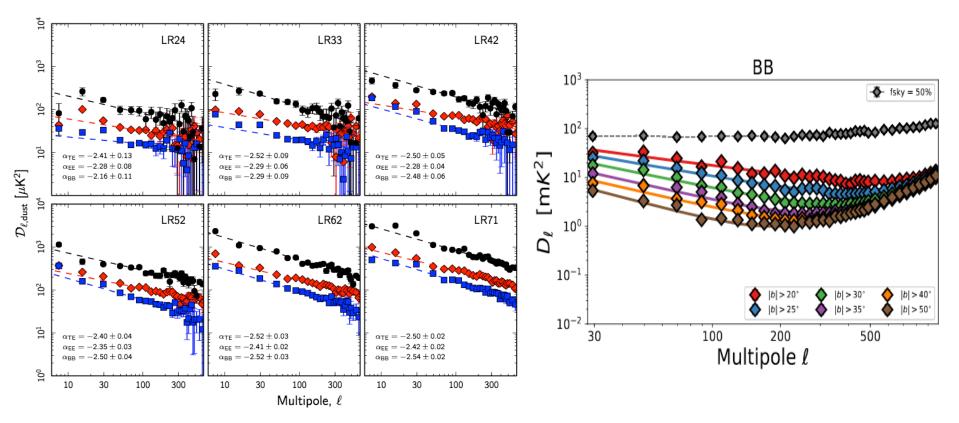

Fig 2 of arxiv/1801.04945 – Planck dust analysis

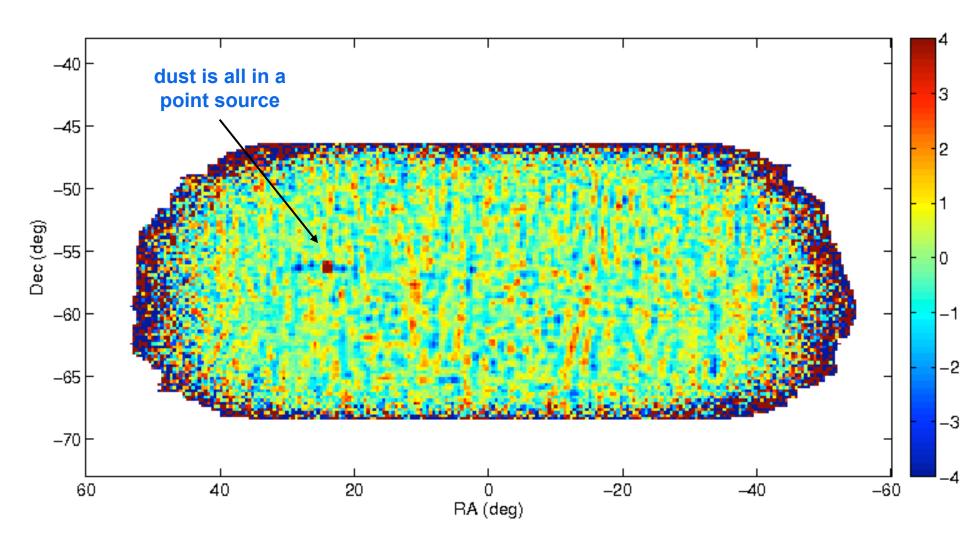

Fig 2 of arxiv/1802.01145. – S-PASS sync analysis

- Averaged over large regions of sky it is an empirical fact that dust and sync have roughly power law angular power spectra
- > Not enough signal-to-noise in Planck data to investigate fluctuations about this behavior for small sky patches

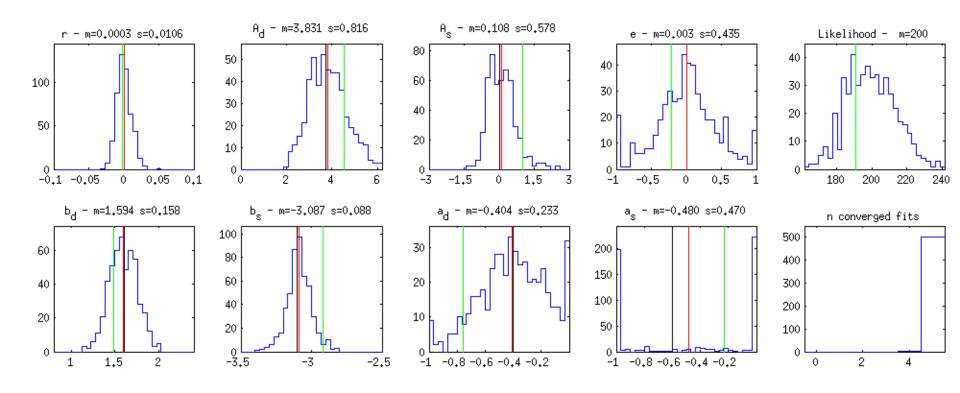

#### Does it matter that dust is not a Gaussian random field?

- ➤ The error bars we put on power spectrum plots assume the sky pattern is a Gaussian random fields
- Nominally our Hamimeche and Lewis (HL) based likelihood does as well(?)
- ➤ To empirically test if it matters we make some sims where the dust sky pattern is extremely non-Gaussian make it a single point source at some random location on the field
- ➤ Then run these lensed-LCDM+dust+noise realizations through the analysis pipeline as usual...
- ➤ In a power spectrum sense such dust realizations have only a single (amplitude) degree of freedom so in a sense the exact opposite of Gaussian (maximal degrees of freedom)

#### Simulated 150GHz lensed-LCDM+"dust"+noise Q Map

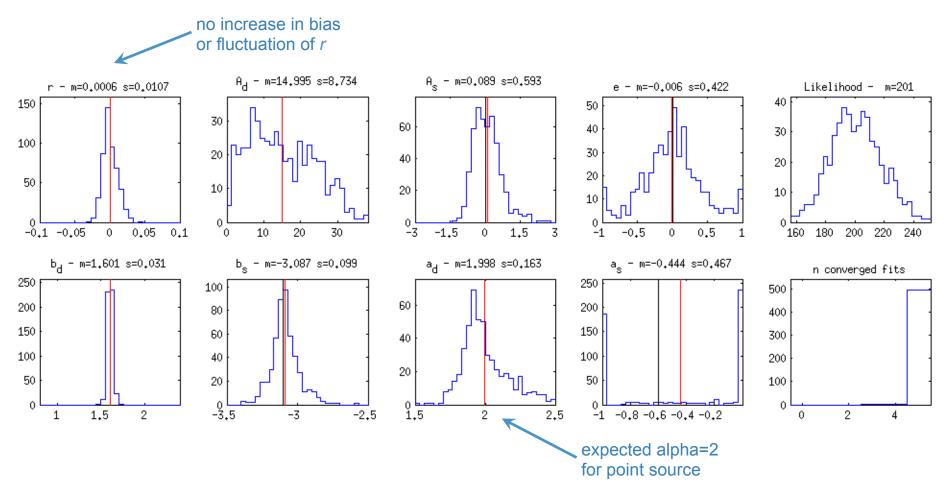

## Maximum Likelihood Search Results on lensed-LCDM+dust+noise Simulations Standard Gaussian dust realizations

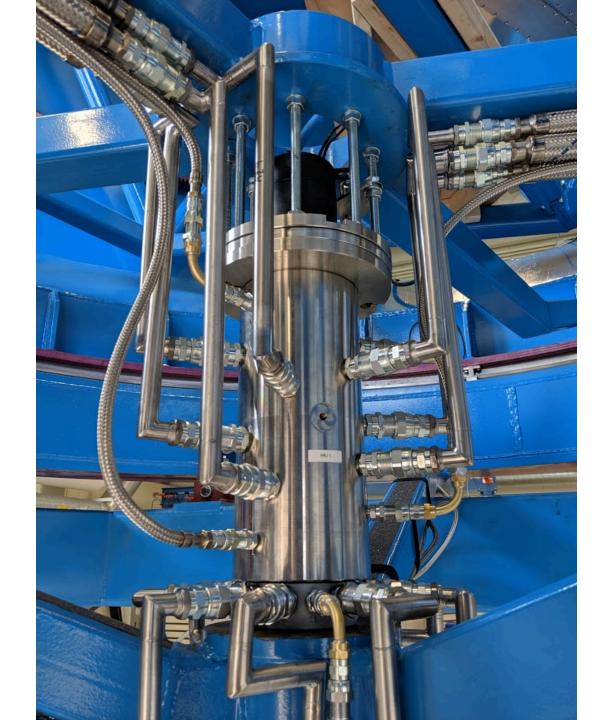

Each panel is a model parameter – numbers above are mean and sigma over sim realizations Vertical red lines are mean value over realizations, black is sim input value (and green is real data value)

## Maximum Likelihood Search Results on lensed-LCDM+dust+noise Simulations Special "point source dust" realizations

Each panel is a model parameter – numbers above are mean and sigma over sim realizations Vertical red lines are mean value over realizations, black is sim input value (and green is real data value)

## What limits BK18?

- $\clubsuit$  BK18 mainline simulations with dust and lensing give  $\sigma(r)=0.009$
- Running without foreground parameters on simulations where the dust amplitude is set to zero gives  $\sigma(r)=0.007$

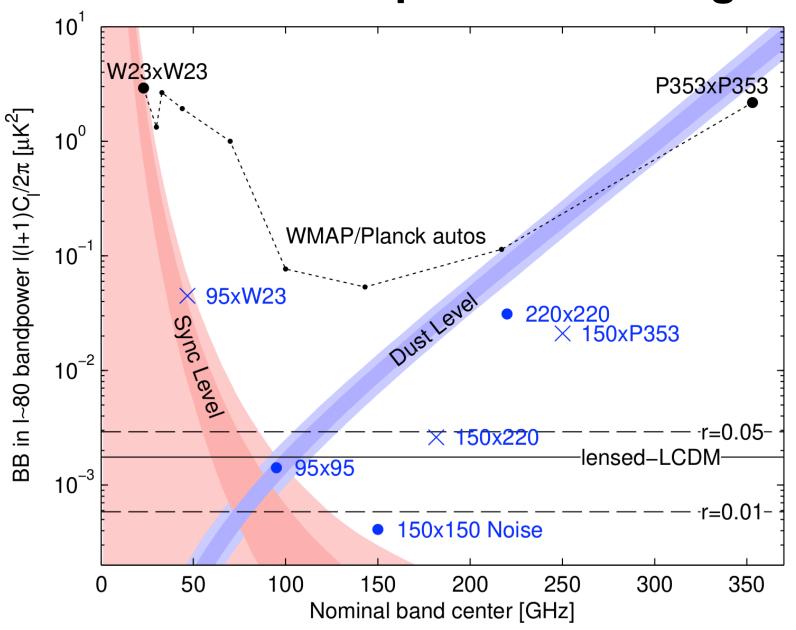

The above is as it should be - we have correctly tuned the relative sensitivity of the 95/150/220 bands such that we don't suffer much penalty due to the presence of foregrounds.

A Running on simulations which contain no lensing gives  $\sigma(r)=0.004$ 

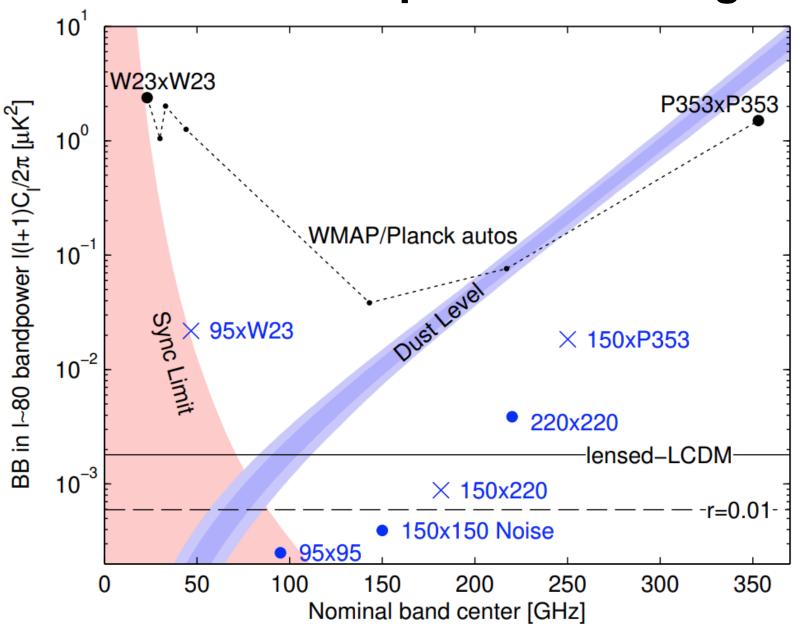

The sample variance of the achromatic lensing foreground is a major limiting factor - we need delensing via high resolution measurements.

Running without foreground parameters on simulations which have neither dust or lensing gives  $\sigma(r)=0.002$ 

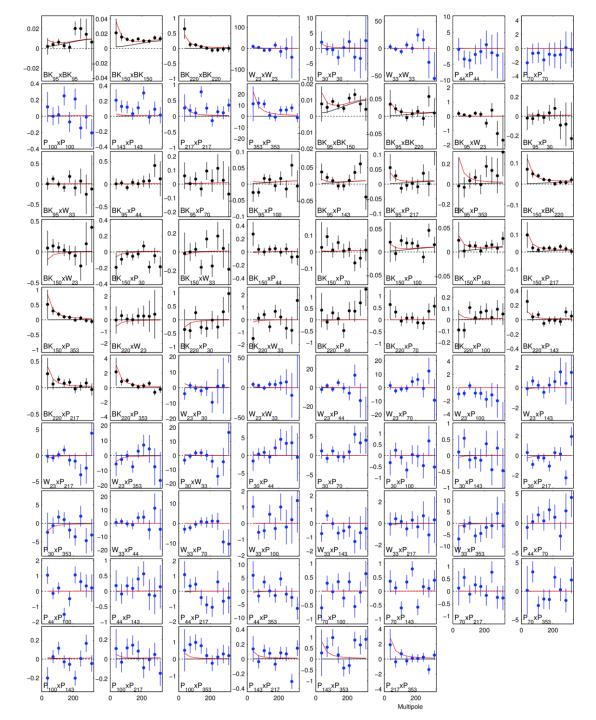

## BK15 ell=80 bandpower noise/signal

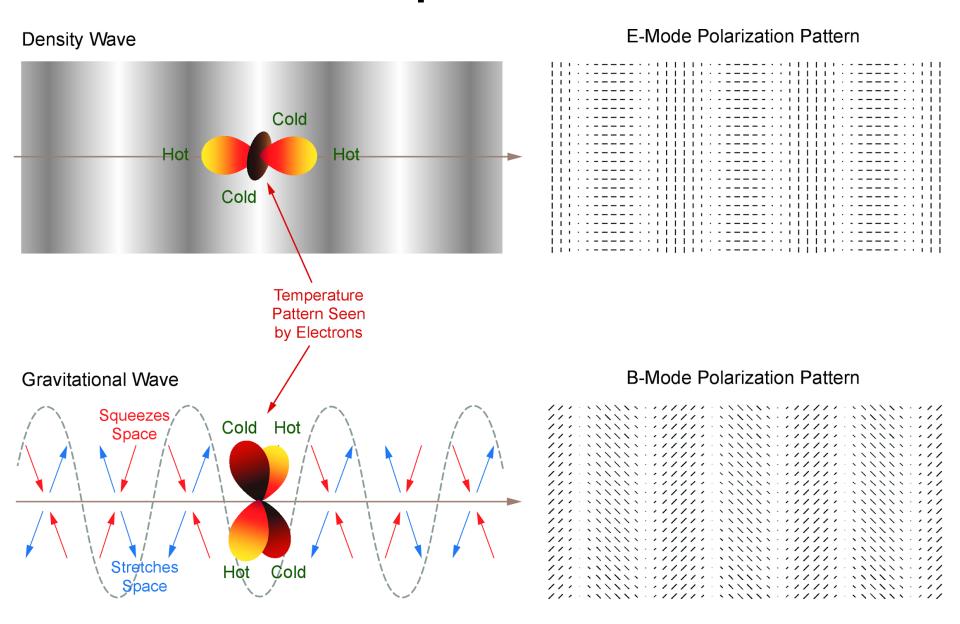

## BK18 ell=80 bandpower noise/signal

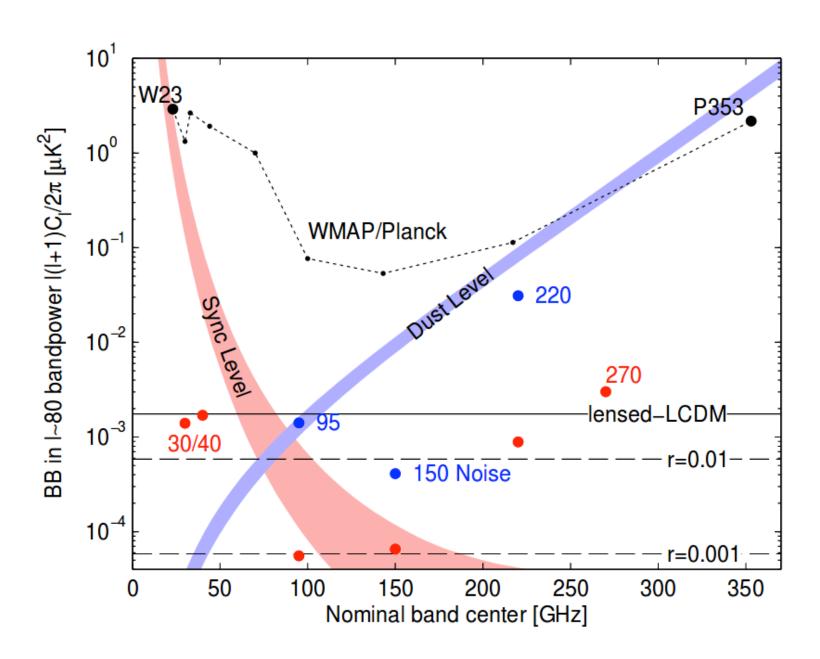

Take all possible auto- and cross spectra between the BICEP/Keck, WMAP, and Planck bands (78 of them)

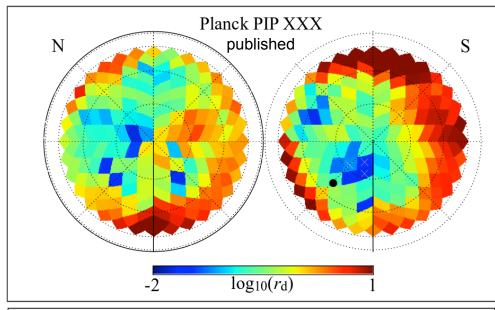

## **CMB** polarization

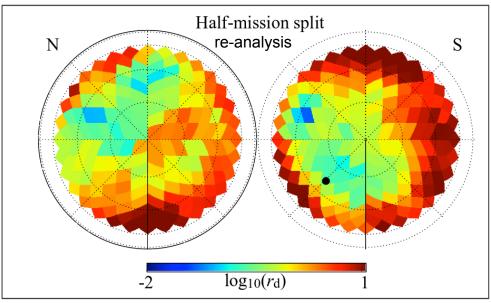

## **BK23 Noise levels**

# Is there a cleaner small field than the BICEP/Keck field?

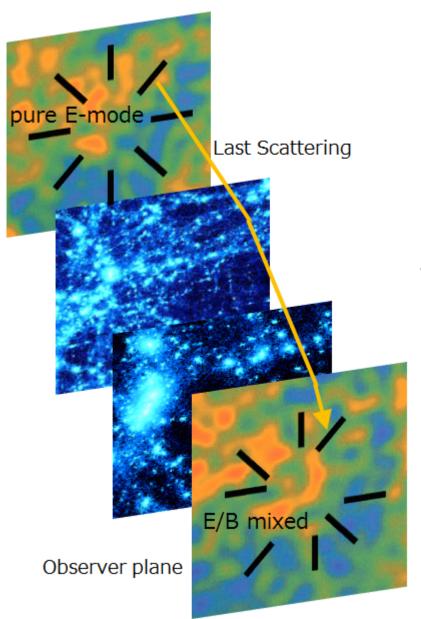

- The Planck 353GHz Q/U maps hit their noise floor in the cleanest regions
  - From this data it is not really possible to tell if there are cleaner small regions than the BICEP/ Keck field
- When we attempt to reproduce the Planck PIPXXX analysis we find that the apparent cleaner regions shift around depending on the data split selected
- ❖ The BK patch is currently the only low dust field where we actually know the dust level!

## Slides summarizing BK-VIII: Measurement of Gravitational Lensing from Large-scale B-mode Polarization

## Measurement of Gravitational Lensing

 Gravitational lensing converts some of the E mode into B mode

Zaldarriaga & Seljak (1998)

$$B_{\vec{\ell}} = \int d\vec{L} \, w_{\vec{\ell}, \vec{L}} E_{\vec{L}} \kappa_{\vec{\ell} - \vec{L}}$$

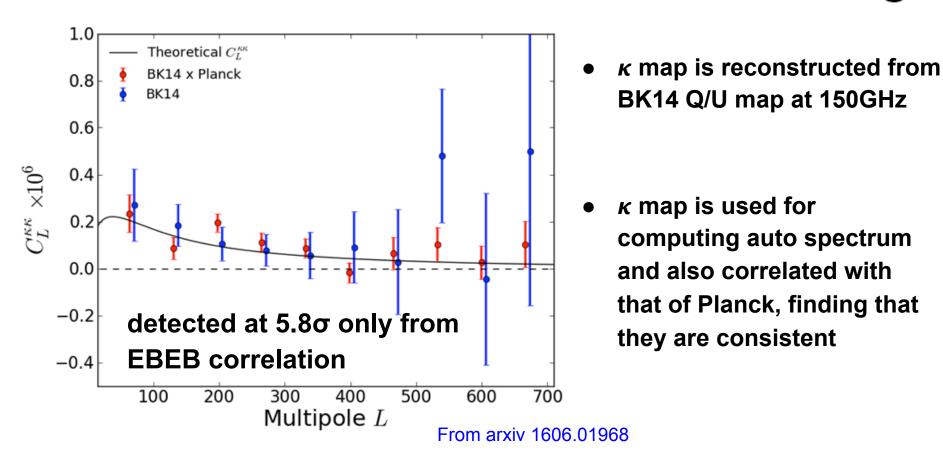

**Lensing convergence** 

Lensing B mode behaves as 5uK' white noise at large angular scales

(e.g. Lewis & Challinor 2006)

Despite our modest angular resolution (0.5deg), the excellent sensitivity (~3μΚ') of our maps makes it possible to directly reconstruct lensing signals using only information at larger angular scales (ℓ≤700).

## Measurement of Gravitational Lensing

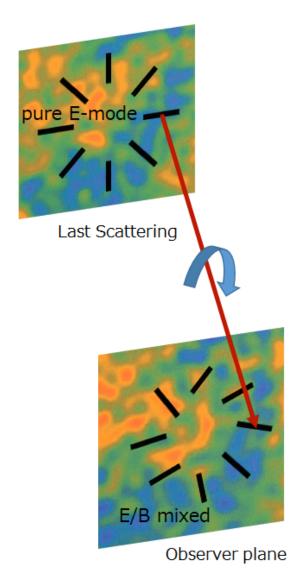

Measured amplitude is in good agreement with the BB results, and we can start to constrain alternative B-mode sources!

(cosmic string, magnetic field, axion, modified gravity,...)

# Slides summarizing BK-IX: New Bounds on Anisotropies of CMB Polarization Rotation and Implications for Axion-Like Particles and Primordial Magnetic Fields

#### Cosmological origins of anisotropies of polarization rotation

#### Axion-like particles

String theory generally predicts presence of axion-like particles coupled with electromagnetic fields

(e.g. Pospelov+'09, Caldwell+'11)

Lagrangian 
$$\supset \frac{\phi}{2f_a} F_{\mu\nu} \tilde{F}^{\mu\nu}$$

Coupling constant

This coupling leads to spatial variation of polarization angle rotation

rotation angle 
$$\alpha(n) = \frac{\Delta \phi(n)}{f_a}$$
 Changes in phi during photon propagation

#### Primordial magnetic fields

Lead to the polarization rotation by the Faraday rotation

Total rotation angle

(e.g. Kosowsky&Loeb'96, Harari+'97)

$$\alpha(n) = \frac{3c^2}{16\pi e^2} v^{-2} \int \dot{\tau} \, \vec{B} \cdot d\vec{l}$$
Magnetic field

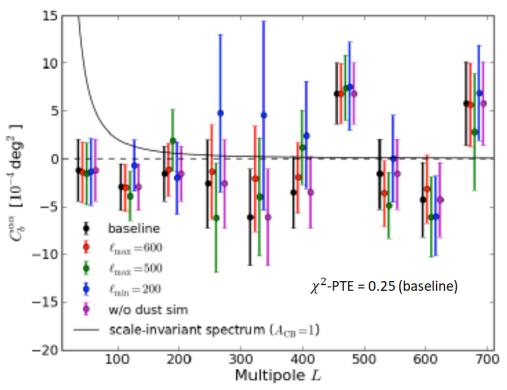

Measurement of the anisotropic polarization rotation is a unique probe of the early universe and provides important implications for high energy physics!

#### Measurement of the polarization rotation spectrum

#### Analysis Method

Anisotropic pol. rotation leads to mode-coupling between E and B modes as similar to lensing. Thus we can apply the same analysis method as in the lensing case but using different weight function to optimally reconstruct rotation angle

#### Measured spectrum

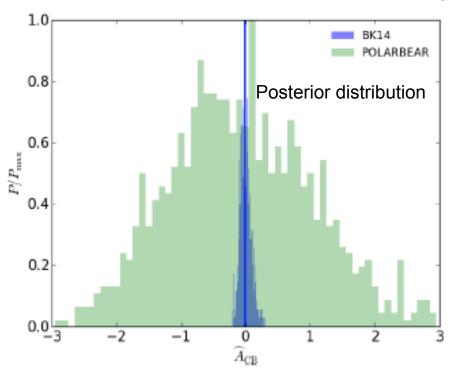

- The spectrum is consistent with null
   (even if we change the analysis choices)
- The reconstructed spectra measured from our 14 jackknife maps are also consistent with null
- Instrumental relative pol. rotation < 1% of the 1 sigma statistical error

From arxiv 1705.02523

#### Comparison w/ previous works & cosmological implications

#### • Improved constraints on inflationary pol. rotation spectrum

If sources of the pol. rotation are originated from inflation, the expected rotation spectrum has the following scale-invariant shape

$$\frac{L(L+1)}{2\pi}C_L^{\alpha\alpha} = A_{CB} \times 10^{-4}$$

Compared to previous attempts, we improve the constraints on this inflationary rotation spectrum by an order of magnitude.

$$A_{\rm CB} \leq 0.33 \text{ at } 95\%$$

From arxiv 1705.02523

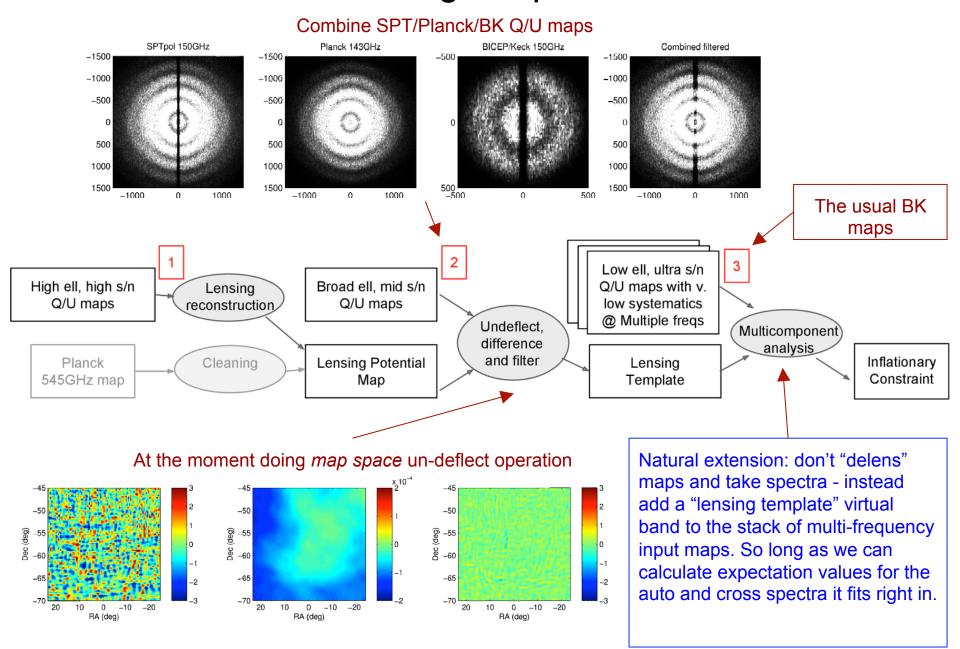

#### Implications

The above results lead to constraints on

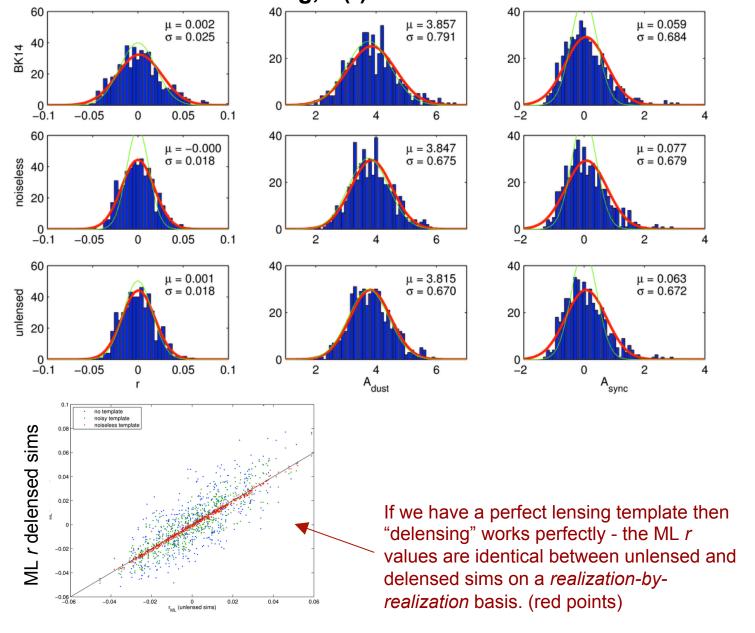

- 1) Coupling constant of the Chern-Simons term  $f_a \geq 1.7 \times 10^2 \frac{H_I}{2\pi}$  an order of magnitude better than Pospelov et al. (2009) PRL
- 2) Strength of the scale-invariant PMF smoothed over 1Mpc  $B_{1Mpc} \leq 30$ nG.

## **Delensing slides**

#### How to make the lensing template:

Perfect lensing template in multicomponent analysis matches performance from sims that do not include CMB lensing,  $\sigma(r) \sim 0.018$  for BK14.

## **Current delensing efforts**

Analysis now includes simulations of more realistic lensing template, using Planck CIB map as Φ tracer and SPT+Planck+BK E modes. Similar to Manzotti et al SPT delensing paper, but using Planck CIB instead of Herschel for sky coverage.

Expect ~10% improvement in  $\sigma(r)$ Limited by  $\Phi$  map, not E modes

Future delensing with BICEP Array + SPT-3G will reconstruct Φ from high resolution CMB maps.

- Need to characterize internal delensing biases
- Expect to achieve > 60% reduction in lensing BB power
